1 Introduction

ICS (Integrated Canonizer and Solver) is a decision procedure developed at SRI International. It efficiently decides formulas in a useful combination of theories, and it provides an API that makes it suitable for use in applications with highly dynamic environments such as proof search or symbolic simulation.

The theory decided by ICS is a quantifier-free, first-order theory of equality with terms built from

- uninterpreted function symbols,
- arithmetic operators including inequalities and number predicates,
- tupling operators and tuple projection,
- S-expressions,
- array lookup and update,
- operators on fixed-sized bitvectors.

This theory is particularly interesting for many applications in the realm of software and hardware verification. Combinations of a multitude of datatypes occur naturally in system specifications and the use of uninterpreted function symbols has proven to be essential for many real-world verifications.

The core of ICS is a congruence closure procedure [RS01, ?] for the theory of equality and disequality with both uninterpreted and interpreted function symbols. The concepts of canonization and solving have been extended to include inequalities over linear arithmetic terms. The theory supported by ICS currently includes:

- The usual propositional constants `true`, `false`.
- Equality (`=`) and disequality (`/=`).
- Rational constants and the arithmetic operators `+`, `*`, `-`; multiplication is restricted to multiplication by constants. Arithmetic predicates include an integer test and the usual inequalities `<`, `<=`, `>`, `>=`.
- Lookup a`[`x`]` and update a`[`x`:=`t`]` operations for arrays a.
- Fixed-sized bitvectors including constants such as `0b101`, concatenation (`conc[3,4]`$(b_1$`,`b_2`)`), extraction (b`[`i`:`j`]`), bit-wise operations like bit-wise conjunction (b_1 `&&` b_2), and built-in arithmetic relations such as `add(`b_1`,`b_2`,`b`)`. This latter constraint encodes the fact that the sum of the unsigned interpretations of b_1 and b_2 equals the unsigned interpretation of b. Fixed-sized bitvectors are decided using the techniques described in [MR98].

ICS is capable of deciding sequents such as

- `x+2 = y |- f(a[x:=3][y-2]) = f(y-x+1)`
- `f(y-1)-1 = y+1, f(x)+1 = x-1, x+1 = y |- false`
- `f(f(x)-f(y)) /= f(z), y <= x, y >= x+z, z >= 0 |- false`

These formulas contain uninterpreted function symbols such as `f` and interpreted symbols drawn from the theories of arithmetic and the functional arrays. The list of interpreted theories above is open-ended in the sense that new theories can be added to ICS as long as they are canonizable and algebraically solvable. The modular design of ICS—both the underlying algorithms and their implementation—supports such extensions.

One of the main problems in employing decision procedures effectively is due to the fact that verification conditions usually depend on large contexts. In addition, these contexts change frequently in applications such as symbolic simulation or backtracking proof search. Consequently, decision procedure systems that are effective in these domains must not only be able to build up contexts incrementally but they must also support efficiently switching between a multitude of contexts. ICS meets these criteria in that all of its main algorithm work incrementally and the data structures for representing contexts are persistent, that is, operations on data structures do not alter the previous values of data and *undo* operations are therefore basically for free.

ICS is implemented in Ocaml [Oca], which offers satisfactory run-time performance, efficient garbage collection, and interfaces well with other languages like C. The implementation of ICS is based on optimization techniques such as hash-consing [Fil00] and efficient data structures like Patricia trees [OG98] for representing sets and maps efficiently.

There is a well-defined API for manipulating ICS terms, asserting formulas to the current database, switching between databases, and functions for canonizing terms. This API is packaged as a C library, an Ocaml module, and a CommonLisp interface. The C library API, for example, has been used to connect ICS with PVS [ORS92], and both an interaction and a batch processing capability have been built using this API.

Using ICS as the underlying decision procedure of PVS, we experience speed-ups of several orders of magnitude (compared with the PVS default decision procedures) for selected problems. and for typical problems we are usually able to process several thousand theorems every second. The efficiency and scalability of ICS in processing formulas, the richness of its API, and its ability for fast context-switching should make it possible to use it as a black box for discharging verification conditions not only in a theorem proving context but also in a multitude of applications like static analysis, abstract interpretation, extended type checking, symbolic simulation, model checking, or compiler optimization.

1.1 Availability

For academic, non-commercial use ICS is available free of charge under a license agreement with SRI. ICS is also an integral part of PVS 3.0. The complete sources and documentation of ICS are available at

www.icansolve.com

There one can also find the ICS license.

1.2 Organization

This document describes the interfaces and implementation aspects of the ICS decision procedures. The various modules of the implementation are not presented in topological order with respect to their inter-dependencies, but rather in a more logical order. However, it may help to have in mind the graph of dependencies, which is the following:

2 Installation

Distribution. The file `ics.tar.gz` can be downlowded from www.icansolve.com. Unpack this file using

```
> zcat ics.tar.gz | tar xvf -
```

This creates a directory `./ics` with the following files and directory.

`Makefile.in`	:	Template for generating `Makefile`.
`fm-license.in`	:	Noncommercial license.
`bin/`	:	Binaries
`configure`	:	Configuration script
`lib/`	:	Archives and shared object files
`tests/`	:	Various benchmarks
`README`	:	Short installation guide
`doc/`	:	Documentation
`obj/`	:	Object files
`src/`	:	Source files
`ics/`	:	Shell script for invoking ICS interactor

The latest version of ICS can be obtained by using the CVS checkout command

```
> cvs co ics -d $CVS_root
```

where `CVS_root` is set to

```
/project/pvs2/cvsroot
```

Requirements. ICS is written mainly in Ocaml, and it uses uses arbitrary precision rational numbers from the GNU multi-precision library (GMP). To compile ICS one needs to install:

- The autoconf package is freely available at http://www.gnu.org/software/autoconf/.
- Ocaml version 3.04 or later. Freely available at http://caml.inria.fr.
- GNU MP version 3.0 or later. This package is freely available at http://www.swox.com/gmp/.

So far, we have only compiled ICS on Linux Redhat 6.0, but it should be possible to compile it on a wide range of machines and operating systems.

Installation. A configuration `./configure` is generated from `./configure.in` in the ICS home directory using

```
> autoconf
```

The configuration script generates a `Makefile` from the `Makefile.in`.

```
> ./configure [--with-gmp=/path/to/gmp]
```

Then, `make` compiles ICS on your machine.

```
> make
```

Binaries are placed in `./bin/$(ARCH)/` and the libraries in `./lib/$(ARCH)/`, where `ARCH` is the architecture guessed by the configuration script. The build directory is `./obj/$(ARCH)/`, and the generated binary and byte code are put in `./bin/$(ARCH)/`.

3 The ICS interactor

The interactor permits to process formulas interactively and to explore the database. We give an overview of the capabilities of ICS using various little examples.

The interactor is started with `./ics` in the ICS home directory.

```
% ics
ICS interpreter. Copyright (c) 2001 SRI International.

>
```

The '>' is the prompt and ICS is ready to interpret your commands.

3.1 The Command Language

The ICS command language realizes a *ask/tell* interface to a context consisting of known facts. When invoking the interactor, this context is empty.

Asserting facts.

`assert` *atom*`.`

An *atom* is asserted to the current context using the `assert` command. There are three possible outcomes:

1. *atom* is inconsistent with respect to the current context. In this case, `assert` leaves the current context unchanged and outputs `Unsat.` on the standard output.

2. *atom* is valid in the current context. Again, the the current context is left, and now `Valid.` is output.

3. Otherwise, in case *atom* is satisfiable but not valid, the context is modified to include new information obtained from *atom*.

Resetting.

`reset .`

Reinitializes all internal data structures including setting the current logical context to the empty context.

Clearing current logical context.

`forget .`

Resets the current logical context to the empty context. In contrast to `reset`, all other ICS data structures are left unchanged.

Sigmatization.

`sigma` (*term*| *atom*) .

Computes the normal form of a term or an atom using theory-specific canonizers for terms in interpreted theories and some builtin simplifications for uninterpreted terms. This command leaves the current state unchanged.

Canonization.

`can` (*term*| *atom*) .

For a term `t`, `can t` returns a variable, which is a canonical representative of `t`.

For an atom `a`, `can a` returns a semicanonical form which reduces to the atom `True` if [a] can be shown to hold in the current context, and `False` if `a` can be shown to be inconsistent. Otherwise, an atom [b] is returned which is equivalent to [a] in the current context.

[can] might involve a state change in that renaming variables of the form `v!i` are generated and equalities `v!i = a'` for subterms of `a` are added to the logical context.

Solving.

`solve` (`a` | `t bv`) *term*= *term*.

Theory-specific solver for input equality. Returns either a solved list of equalities with variables on the lhs which is equivalent to the input equality or `Unsat.` if the input equality is unsatisfiable. There are solvers for linear arithmetic (`a`), tuples (`t`), and bitvectors (`bv`).

Logical Context.

`ctxt .`

Return the set of atoms asserted in the current logical context. These atoms are not necessarily in canonical form.

Variable Partitioning.

`partition .`

Returns the set of all known equalities between variables.

Solution sets.

`solution (u | a | t bv) .`

Returns the solution set corresponding to the specified theory, which consists of a set of equalities `x = a` with `x` a variable and `a` a term built-up from variables and function symbols in the specified theory. Variables on the rhs might either be external variables or fresh variables introduced by a theory-specific solver. For all interpreted theories, that is, for all theories except for the uninterpreted theory `u`, the equations in a solved form are actually solved in that variables `x` on a rhs do not occur in any of the lhs.

Finds in solution sets.

`find (u | a | t bv)` *term* .

If `x = t` is in the specified solution set (see command `solution`), then `find . x` returns `t` and otherwise `x`.

Inverse Finds in solution sets.

`find (u | a | t bv)` *term* .

If `x = t` is in the specified solution set (see command `solution`), then `inv . t` returns `x` and otherwise `Unsat.`.

Comparison.

term`«` *term* .

Syntactic comparison of two terms. `s « t` returns `Less` (`Equal`, `Greater` if `s` is less (equal, greater) than `t` according to the builtin term ordering.

Arithmetic Constraints.

`cnstrnt` *term* .

Compute an arithmetic constraint for the argument term in the current context using abstract interpretation on intervals. Returns `None.` if no such constraint could be deduced.

Disequalities.

`diseq` *term*.

Returns a list of variables known to be disequal in the current context.

Displaying the context.

`show` .

Displays the variable partitioning, theory-specific solution sets, and disequality information. See also the commands `partition`, `solution`, and `diseq`.

Term Definition.

`def` *var* `:=` *term*.

Extend the symbol table with a definition *var*for term *term*. In such a context, variable *var*is always expanded to *term*.

Type Definition.

`type` *var* `:=` *cnstrnt*.

Extend the symbol table with a definition *var*for the constraint *cnstrnt*. In such a context, variable *var*can always be used instead of the corresponding constraint.

Signature Declaration.

`sig` *var* `:=` `bv[int]` .

Declare a variable to be interpreted over the set of bitvectors of width `int`. This context information is used for inferring parameters when applying infix bitvector operators.

Symbol Table.

`symtab` {*var*} .

`symtab` display the current symbol table, and `symtab` *var*displays the symbol table entry for *var*.

Saving the current logical context.

`save` {*var*} .

Adding a symbol table entry for the current logical state.

Restoring logical contexts.

`restore` $\{var\}$.

Updating the current logical state to be the state named by *var*in the symbol table.

Removing symbol table entries

`remove` $\{var\}$.

Remove the symbol table entry corresponding to *var*.

Verbose.

`verbose` *int* .

Determines the amount of trace information displayed on standard output. The larger the argument the more information is output.

Garbage Collection.

`gc` .

This command results in a logical context which is equivalent to the current one but redundant variables are eliminated.

Debugging.

`drop` .

The effect of this command is to fall back into the Ocaml interactor when running bytecode; otherwise ICS is terminated. This command is mainly for debugging purposes.

Exiting ICS.

`exit` .

Exit the ICS interactor. Alternatively, `Ctrl-D` can be used.

4 Application Programming Interface

Usually, the capabilites of ICS are not accessed through the interactor but rather through its application programming interface. Currently, we support interfaces for C, Fortran, Lisp, and Ocaml. We first describe the Ocaml interface, since the interfaces for the other programming languages are automatically generated from this one.

4.1 Caml interface

Interface for module Ics.mli

1. Module *Ics*: the application programming interface to ICS for asserting formulas to a logical context, switching between different logical contexts, and functions for manipulating and normalizing terms.

There are two sets of interface functions. The functional interface provides functions for building up the main syntactic categories of ICS such as terms and atoms, and for extending logical contexts using *process*, which is side-effect free.

In contrast to this functional interface, the command interface manipulates a global state consisting, among others, of symbol tables and the current logical context. The *cmd_rep* procedure, which reads commands from the current input channel and manipulates the global structures accordingly, is used to implement the ICS interactor.

Besides functions for manipulating ICS datatypes, this interface also contains a number of standard datatypes such as channels, multiprecision arithmetic, tuples, and lists.

2. Controls. *reset* clears all the global tables. This does not only include the current context but also internal tables used for hash-consing and memoization purposes. *gc* triggers a full major collection of ocaml's garbage collector. *do_at_exit* clears out internal data structures.

val *reset* : *unit* → *unit*

val *gc* : *unit* → *unit*

val *do_at_exit* : *unit* → *unit*

3. *set_maxloops n* determines an upper number of loops in the main ICS loop. $n < 0$ determines that there is no such bound; this is also the default.

val *set_maxloops* : *int* → *unit*

4. Rudimentary control on trace messages, which are sent to *stderr*. These functions are mainly included for debugging purposes, and are usually not being used by the application programmer. *trace_add str* enables tracing of functions associated with trace level *str*. *trace_add* `"all"` enables all tracing. *trace_remove str* removes *str* from the set of active trace levels, and *trace_reset*() disables all tracing. *trace_get*() returns the set of active trace levels.

val *trace_reset* : *unit* → *unit*
val *trace_add* : *string* → *unit*
val *trace_remove* : *string* → *unit*
val *trace_get* : *unit* → *string list*

5. Channels. *inchannel* is the type of input channels. A channel of name *str* is opened with *in_of_string str*. This function raises *Sys_error* in case such a channel can not be opened. *outchannel* is the type of formatting output channels, and channels of this type are

opened with *out_of_string*. *stdin*, *stdout*, and *stderr* are predefined channels for standard input, standard output, and standard error. *flush* flushes the *stdout* channel.

type *inchannel* = *in_channel*
type *outchannel* = *Format.formatter*

val *channel_stdin* : *unit* → *inchannel*
val *channel_stdout* : *unit* → *outchannel*
val *channel_stderr* : *unit* → *outchannel*
val *inchannel_of_string* : *string* → *inchannel*
val *outchannel_of_string* : *string* → *outchannel*

val *flush* : *unit* → *unit*

6. Multi-precision rational numbers. *num_of_int n* injects an integer into this type, *num_of_ints n m*, for $m \neq 0$, constructs a normalized representation of the rational n/m in q, *string_of_num q* constructs a string (usually for printout) of a rational number, and *num_of_string s* constructs a rational, whenever s is of the form `"n/m"` where n and m are naturals.

type q

val *num_of_int* : *int* → q
val *num_of_ints* : *int* → *int* → q
val *ints_of_num* : q → *string* × *string*
val *string_of_num* : q → *string*
val *num_of_string* : *string* → q

7. Names. *name_of_string* and *name_to_string* coerce between the datatypes of strings and names. These coercions are inverse to each other. *name_eq* tests for equality of names in constant time.

type *name*

val *name_of_string* : *string* → *name*
val *name_to_string* : *name* → *string*
val *name_eq* : *name* → *name* → *bool*

8. Arithmetic constraints. A constraint consists of a domain restriction *Int* or *Real* , a real interval, and a set of disequality numbers. A real number satisfies such a constraint if, first, it satisfies the domain restriction, second, it is a member of the interval, and, third, it is none of the numbers in the disequality set.

cnstrnt_of_string str parses the string *str* according to the nonterminal *cnstrnteof* in module *Parser* (see its specification in file parser.*mly*) and produces the corresponding constraint representation. In contrast, *cnstrnt_input* in parses the concrete syntax of constraints from the input channel in. Constraints c are printed to the output channel *out* using *cnstrnt_output out c* and to the standard output using *cnstrnt_pp c*.

For the definition of constraint constructors see Module *Cnstrnt*. *cnstrnt_mk_int*() constructs an integer constraint, *cnstrnt_mk_nat*() a constraint for the natural numbers,

cnstrnt_mk_singleton q is the constraint which holds only of q, *cnstrnt_mk_diseq q* holds for all reals except for q, *cnstrnt_mk_oo l h* constructs an open interval with lower bound l and upper bound h, *cnstrnt_mk_oc l h* is the left-open, right-closed interval with lower bound l and upper bound h, *cnstrnt_mk_co l h* is the left-closed, right-open interval with lower bound l and upper bound h, *cnstrnt_mk_cc l h* is the closed interval with lower bound l and upper bound h.

The intersection of two constraints c, d is computed by *cnstrnt_inter c d*, that is, a real q is in both c and d iff it is in *cnstrnt_inter c d*.

type *cnstrnt*

val *cnstrnt_of_string* : *string* → *cnstrnt*
val *cnstrnt_input* : *inchannel* → *cnstrnt*
val *cnstrnt_output* : *outchannel* → *cnstrnt* → *unit*
val *cnstrnt_pp* : *cnstrnt* → *unit*

val *cnstrnt_mk_int* : *unit* → *cnstrnt*
val *cnstrnt_mk_nonint* : *unit* → *cnstrnt*
val *cnstrnt_mk_nat* : *unit* → *cnstrnt*
val *cnstrnt_mk_singleton* : *q* → *cnstrnt*
val *cnstrnt_mk_diseq* : *q* → *cnstrnt*
val *cnstrnt_mk_oo* : *q* → *q* → *cnstrnt*
val *cnstrnt_mk_oc* : *q* → *q* → *cnstrnt*
val *cnstrnt_mk_co* : *q* → *q* → *cnstrnt*
val *cnstrnt_mk_cc* : *q* → *q* → *cnstrnt*
val *cnstrnt_mk_lt* : *q* → *cnstrnt*
val *cnstrnt_mk_le* : *q* → *cnstrnt*
val *cnstrnt_mk_gt* : *q* → *cnstrnt*
val *cnstrnt_mk_ge* : *q* → *cnstrnt*

val *cnstrnt_inter* : *cnstrnt* → *cnstrnt* → *cnstrnt*

9. Abstract interval interpretation. A real number x is in *cnstrnt_add c d* iff there are real numbers y in c and z in d such that $x = y + x$. Likewise, x is in *cnstrnt_multq q c* iff there exists y in c such that $x = q \times y$. In constrast to these exact abstract operators, *cnstrnt_mult* and *cnstrnt_div* compute overaprroximations, that is, if x in c and y in d then there exists a z in *cnstrnt_mult c d* (*cnstrnt_div c d*) such that $z = x \times y$ ($z = x/y$).

val *cnstrnt_add* : *cnstrnt* → *cnstrnt* → *cnstrnt*
val *cnstrnt_multq* : *q* → *cnstrnt* → *cnstrnt*
val *cnstrnt_mult* : *cnstrnt* → *cnstrnt* → *cnstrnt*
val *cnstrnt_div* : *cnstrnt* → *cnstrnt* → *cnstrnt*

10. Theories. A theory is associated with each function symbol. These theories are indexed by naturals between 0 and 8 according to the following table

0 Theory of uninterpreted function symbols. 1 Linear arithmetic theory. 2 Product theory. 3 Bitvector theory. 4 Coproducts. 5 Power products. 6 Theory of function abstraction and application. 7 Array theory. 8 Theory of bitvector interpretation(s).

type $th = int$

val $th\_to\_string : th \rightarrow string$

11. Function symbols. These are partitioned into uninterpreted function symbols and function symbols interpreted in one of the builtin theories. For each interpreted function symbol there is a recognizer function is_xxx. Some values of type sym represent families of function symbols. The corresponding indices can be obtained using the destructor d_xxx functions (only after checking that is_xxx holds.

type sym

val $sym\_is\_uninterp : sym \rightarrow bool$
val $sym\_is\_interp : th \rightarrow sym \rightarrow bool$

12. sym_eq tests for equality of two function symbols.

val $sym\_eq : sym \rightarrow sym \rightarrow bool$

13. sym_cmp provides a total ordering on function symbols. It returns a negative integer if $s < t$, 0 if s is equal to t, and a positive number if $s > t$.

val $sym\_cmp : sym \rightarrow sym \rightarrow int$

14. Arithmetic function symbols are either numerals, addition, or linear multiplication.

val $sym\_is\_num : sym \rightarrow bool$
val $sym\_d\_num : sym \rightarrow q$

val $sym\_is\_add : sym \rightarrow bool$

val $sym\_is\_multq : sym \rightarrow bool$
val $sym\_d\_multq : sym \rightarrow q$

Symbols interpreted in the theory of products.

val $sym\_is\_tuple : sym \rightarrow bool$

val $sym\_is\_proj : sym \rightarrow bool$
val $sym\_d\_proj : sym \rightarrow int \times int$

15. Symbols interpreted in the theory of coproducts.

val $sym\_is\_inl : sym \rightarrow bool$
val $sym\_is\_inr : sym \rightarrow bool$
val $sym\_is\_outl : sym \rightarrow bool$
val $sym\_is\_outr : sym \rightarrow bool$

16. Symbols in the bitvector theory.

val $sym\_is\_bv\_const : sym \rightarrow bool$

val $sym\_is\_bv\_conc : sym \rightarrow bool$
val $sym\_d\_bv\_conc : sym \rightarrow int \times int$

val *sym_is_bv_sub* : *sym* → *bool*
val *sym_d_bv_sub* : *sym* → *int* × *int* × *int*

val *sym_is_bv_bitwise* : *sym* → *bool*
val *sym_d_bv_bitwise* : *sym* → *int*

17. Symbols from the theory of power products.

val *sym_is_mult* : *sym* → *bool*

val *sym_is_expt* : *sym* → *bool*

18. Symbols from the theory of function abstraction and application.

val *sym_is_apply* : *sym* → *bool*
val *sym_d_apply* : *sym* → *cnstrnt option*

val *sym_is_abs* : *sym* → *bool*

19. Symbols from the theory of arrays.

val *sym_is_select* : *sym* → *bool*

val *sym_is_update* : *sym* → *bool*

20. Symbols from the theory of arithmetic interpretations of bitvectors.

val *sym_is_unsigned* : *sym* → *bool*

21. Terms. Terms are either variables, application of uninterpreted functions, or interpreted constants and operators drawn from a combination of theories..

term_of_string parses a string according to the grammar for the nonterminal *termeof* in module *Parser* (see its specification in file parser.*mly*) and builds a corresponding term. Similary, *term_input* builds a term by reading from an input channel.

term_output out a prints term *a* on the output channel *out*, and *term_pp a* is equivalent to *term_output stdout a*.

Terms are build using constructors, whose names are all of the form *mk_xxx*. For each constructor *mk_xxx* there is a corresponding recognizer *is_xxx* which reduces to true if its argument term has been built with the constructor *mk_xxx*. Moreover, for each constructor *mk_xxx*} above there is a corresponding desctructor *d_xxx* for analyzing the components of such a constructor term.

type *term*

val *term_of_string* : *string* → *term*
val *term_to_string* : *term* → *string*
val *term_input* : *inchannel* → *term*
val *term_output* : *outchannel* → *term* → *unit*
val *term_pp* : *term* → *unit*

22. Equality and Comparison. Comparison *cmp a b* returns either -1, 0, or 1 depending on whether *a* is less than *b*, the arguments are equal, or *a* is greater than *b* according to the builtin term ordering (see *Term.*(<<<)). *term_eq a b* is true iff if *term_cmp a b* returns 0.

val *term_eq* : *term* → *term* → *bool*
val *term_cmp* : *term* → *term* → *int*

23. Given a string s, *term_mk_var* s constructs a variable with name s and *term_mk_uninterp* s *al* constructs an application of an uninterpreted function symbol s to a list of argument terms. If s is any of the builtin function symbols specified in module *Builtin*, the builtin simplifications are applied to this application.

val *term_mk_var* : *string* → *term*

val *term_mk_uninterp* : *string* → *term list* → *term*

24. Arithmetic terms include rational constants built from *term_mk_num* q, linear multiplication *term_mk_multq* q a, addition *term_mk_add* a b of two terms, n-ary addition *term_mk_addl* *al* of a list of terms *al*, subtraction *term_mk_sub* a b of term b from term a, negation *term_mk_unary_minus* a, multiplication *term_mk_mult* a b, and exponentiation *term_mk_expt* n a. These constructors build up arithmetic terms in a canonical form as defined in module *Arith*. *term_is_arith* a holds iff the toplevel function symbol of a is any of the function symbols interpreted in the theory of arithmetic.

val *term_mk_num* : q → *term*
val *term_mk_multq* : q → *term* → *term*
val *term_mk_add* : *term* → *term* → *term*
val *term_mk_addl* : *term list* → *term*
val *term_mk_sub* : *term* → *term* → *term*
val *term_mk_unary_minus* : *term* → *term*

val *term_is_arith* : *term* → *bool*

25. Tuples are built using the *mk_tuple* constructor, and projection of the i-th component of a tuple t of length n is realized using *mk_proj* i n t.

val *term_mk_tuple* : *term list* → *term*
val *term_mk_proj* : *int* → *int* → *term* → *term*

26. Boolean constants.

val *term_mk_true* : *unit* → *term*
val *term_mk_false* : *unit* → *term*

val *term_is_true* : *term* → *bool*
val *term_is_false* : *term* → *bool*

27. Bitvectors

val *term_mk_bvconst* : *string* → *term*
val *term_mk_bvsub* : (*int* × *int* × *int*) → *term* → *term*
val *term_mk_bvconc* : *int* × *int* → *term* → *term* → *term*
val *term_mk_bwite* : *int* → *term* × *term* × *term* → *term*
val *term_mk_bwand* : *int* → *term* → *term* → *term*

val *term_mk_bwor* : *int* → *term* → *term* → *term*
val *term_mk_bwnot* : *int* → *term* → *term*

28. Coproducts.

val *term_mk_inj* : *int* → *term* → *term*
val *term_mk_out* : *int* → *term* → *term*

29. Set of terms.

type *terms*

30. Atoms. *atom_mk_true*() is the trivially true atom, *atom_mk_false*() is the trivially false atom, and given terms *a*, *b*, the constructor *mk_equal a b* constructs an equality constraint, *mk_diseq a b* a disequality constraint, and *atom_mk_in a c* constructs a membership constraint for *a* and a arithmetic constraint *c*. Atoms are printed to *stdout* using *atom_pp*.

type *atom*

val *atom_pp* : *atom* → *unit*

val *atom_of_string* : *string* → *atom*
val *atom_to_string* : *atom* → *string*

val *atom_mk_equal* : *term* → *term* → *atom*
val *atom_mk_diseq* : *term* → *term* → *atom*
val *atom_mk_in* : *cnstrnt* → *term* → *atom*
val *atom_mk_true* : *unit* → *atom*
val *atom_mk_false* : *unit* → *atom*

31. Derived atomic constraints. *atom_mk_int t* restricts the domain of interpretations of term *t* to the integers. Similarly, *atom_mk_real* restricts its argument to the real numbers. *atom_mk_lt a b* generates the constraint `'a'` $<$ `'b'`, *atom_mk_le a b* yields `'a'` $\leq$ `'b'`, *atom_mk_gt a b* yields `'a'` $>$ `'b'`, and *atom_mk_ge a b* yields `'a'` $\geq$ `'b'`.

val *atom_mk_real* : *term* → *atom*
val *atom_mk_int* : *term* → *atom*
val *atom_mk_nonint* : *term* → *atom*

val *atom_mk_lt* : *term* → *term* → *atom*
val *atom_mk_le* : *term* → *term* → *atom*
val *atom_mk_gt* : *term* → *term* → *atom*
val *atom_mk_ge* : *term* → *term* → *atom*

32. Solution sets.

type *solution*

val *solution_apply* : *solution* → *term* → *term*

val *solution_find* : *solution* → *term* → *term*

val *solution_inv* : *solution* → *term* → *term*

val *solution_mem* : *solution* → *term* → *bool*

val *solution_occurs* : *solution* → *term* → *bool*

val *solution_use* : *solution* → *term* → *terms*

val *solution_is_empty* : *solution* → *bool*

33. Logical context. An element of type *state* is a logical context with *state_empty* the empty context. *state_eq s1 s2* is a constant-time predicate for testing for identity of two states. Thus, whenever this predicate holds its arguments states are equivalent, but not necessarily the other way round. Logical contexts are printed using *state_pp*. The set of atoms in a context *s* are obtained with *state_ctxt_of s*.

type *context*

val *context_eq* : *context* → *context* → *bool*

val *context_empty* : *unit* → *context*

val *context_ctxt_of* : *context* → *atom list*

val *context_u_of* : *context* → *solution*

val *context_a_of* : *context* → *solution*

val *context_t_of* : *context* → *solution*

val *context_bv_of* : *context* → *solution*

val *context_pp* : *context* → *unit*

val *context_ctxt_pp* : *context* → *unit*

34. Builtin simplifying constructors.

val *term_mk_unsigned* : *term* → *term*

val *term_mk_update* : *term* → *term* → *term* → *term*
val *term_mk_select* : *term* → *term* → *term*

val *term_mk_div* : *term* → *term* → *term*

val *term_mk_mult* : *term* → *term* → *term*
val *term_mk_multl* : *term list* → *term*
val *term_mk_expt* : *int* → *term* → *term*
(∗ *term_mk_expt n x* represent $x\hat{}n$. ∗)

val *term_mk_apply* : *term* → *term list* → *term*

val *term_mk_arith_apply* : *cnstrnt* → *term* → *term list* → *term*

35. The operation *process s a* adds a new atom *a* to a logical context *s*. The codomain of this function is of type *status*, elements of which represent the three possible outcomes of processing a proposition: 1. the atom *a* is inconsistent in *s*, 2. it is valid, or, 3., it is

satisfiable but not valid. In the third case, a modified state is obtained using the destructor *d_consistent*.

type *status*

val *is_consistent* : *status* → *bool*
val *is_redundant* : *status* → *bool*
val *is_inconsistent* : *status* → *bool*

val *d_consistent* : *status* → *context*

val *process* : *context* → *atom* → *status*

36. Suggesting finite case split.

val *split* : *context* → *atom list*

37. Canonization. Given a logical context *s* and an atom *a*, *can s a* computes a semi-canonical form of *a* in *s*, that is, if *a* holds in *s* it returns *Atom.True*, if the negation of *a* holds in *s* then it returns *Atom.False*, and, otherwise, an equivalent normalized atom built up only from variables is returned. The returned logical state might contain fresh variables.

val *can* : *context* → *atom* → *atom*

38. Given a logical context *s* and a term *a*, *cnstrnt s a* computes the best possible arithmetic constraint for *a* in *s* using constraint informatin in *s* and abstraction interval interpretation. If no such constraint can be deduced, *None* is returned.

val *cnstrnt* : *context* → *term* → *cnstrnt option*

39. An imperative state *istate* does not only include a logical context of type *state* but also a symbol table and input and output channels. A global *istate* variable is manipulated and destructively updated by commands.

40. Initialization. *init n* sets the verbose level to *n*. The higher the verbose level, the more trace information is printed to *stderr* (see below). There are no trace messages for $n = 0$. In addition, initialization makes the system to raise the *Sys.Break* exception upon user interrupt ^C^C. The *init* function should be called before using any other function in this API.

val *init* : *int* × *bool* × *string* × *inchannel* × *outchannel* → *unit*

41. *cmd_eval* reads a command from the current input channel according to the grammar for the nonterminal *commandeof* in module *Parser* (see its specification in file parser.*mly*), the current internal *istate* accordingly, and outputs the result to the current output channel.

val *cmd_rep* : *unit* → *unit*

42. Sleeping for a number of seconds.

val *sleep* : *int* → *unit*

43. Lists.

val $is\_nil : \alpha\ list \to bool$
val $cons : \alpha \to \alpha\ list \to \alpha\ list$
val $head : \alpha\ list \to \alpha$
val $tail : \alpha\ list \to \alpha\ list$

44. Pairs. *pair a b* builds a pair (a, b) and *fst* (*pair a b*) returns a and *snd* (*pair b a*) returns b.

val $pair : \alpha \to \beta \to \alpha \times \beta$
val $fst : \alpha \times \beta \to \alpha$
val $snd : \alpha \times \beta \to \beta$

45. Triples. Accessors for triples (a, b, c).

val $triple : \alpha \to \beta \to \gamma \to \alpha \times \beta \times \gamma$
val $fst\_of\_triple : \alpha \times \beta \times \gamma \to \alpha$
val $snd\_of\_triple : \alpha \times \beta \times \gamma \to \beta$
val $third\_of\_triple : \alpha \times \beta \times \gamma \to \gamma$

46. Quadruples. Accessors for quadruples (a, b, c, d).

val $fst\_of\_quadruple : \alpha \times \beta \times \gamma \times \delta \to \alpha$
val $snd\_of\_quadruple : \alpha \times \beta \times \gamma \times \delta \to \beta$
val $third\_of\_quadruple : \alpha \times \beta \times \gamma \times \delta \to \gamma$
val $fourth\_of\_quadruple : \alpha \times \beta \times \gamma \times \delta \to \delta$

47. Options. An element of type $\alpha\ option$ either satisfies the recognizer *is_some* or *is_none*. In case, *is_some* holds, a value of type α can be obtained by *value_of*.

val $is\_some : \alpha\ option \to bool$
val $is\_none : \alpha\ option \to bool$

val $value\_of : \alpha\ option \to \alpha$

4.2 C Interface

The API for the C programming language is generated automatically from the Ocaml API described above. The generated C file can be found in

```
./obj/$ARCH/ics_stub.c
```

This file contains a C function declaration `ics_xxx` for each of the interface function `xxx` described above. For example, the definition of the function `ics_mk_var` for the `mk_var` constructor is given by the following C code.

```
value* ics_mk_var(char* x1) {
  value* ics_mk_var(char* x1) {
  value* r = malloc(sizeof(value));
```

```
  register_global_root(r);
  *r = 1;
  *r = callback_exn(*ics_mk_var_rv,copy_string(x1));
  if (!Is_exception_result(*r)) { return r; };
  ocaml_error("ics_mk_var",format_caml_exception(Extract_exception(*r)));
  return (value*) 0;
}
```

These interface function translate C arguments to Ocaml values, call the Ocaml function, and translate back the results. In addition, any Ocaml exceptions are caught and handled by the `ocaml_error` function. Curried signatures of the Ocaml functions are uncurried, and list and tuple arguments must be build using the constructors of the interface. The handling of exceptions is determined by the function `ocaml_error`, which has to be provided by the application programmer.

When using `C++` the following declarations are needed to use ICS. First, declare a function `ics_caml_startup` before including `ics.h`.[1]

```
extern "C" {
void ics_caml_startup(int full, char** argv);
#include<ics.h>
}
```

Second, an application-dependent `ics_error` function such as the one below has to be provided.

```
extern "C" {

void ics_error(char * funname, char * message) {
    cerr << "ICS error at " << funname << " : " << message << endl;
    exit(1);
}
}
```

Third, before calling any ICS functionality, call `ics_caml_startup`.

```
int main(int argc, char ** argv) {
    ics_caml_startup(1, argv);
    ...
}
```

A minimal `C++` program for calling ICS can be found in Figure 1. If this program is stored in a file `hello-ics.cpp`, then it can be compiled using

```
g++ hello-ics.cpp -lics
```

Notice that `LD_LIBRARY_PATH` variable should be such that the shared object file `libics.so` can be found in the linking stage.

[1] Within the `extern "C"` directive, the `C++` compiler does not rename functions.

```
#include<iostream.h>
extern "C" {
void ics_caml_startup(int full, char** argv);
#include<ics.h>
}

int main(int argc, char ** argv) {
    ics_caml_startup(1, argv);
    cout << "ICS: Hello World\n";
}

extern "C" {
void ics_error(char * funname, char * message) {
    cerr << "ICS error at " << funname << " : " << message << endl;
    exit(1);
}}
```

Figure 1: Minimal setup for calling ICS.

4.3 Lisp Interface

The Lisp API for ICS builds on the C interface and uses the foreign function interface of Allegro Common Lisp 6.0. For each function `xxx` in the API a foreign function declaration `ics_xxx` is generated. These definitions are collected in the file

```
./obj/$ARCH/ics.lisp
```

The Lisp interface ensures that the Lisp and the Ocaml garbage collector cooperate.

5 Data Structures

Terms and atoms are the main syntactic categories of ICS, where atoms are equalities or disequalities over terms or interval constraints over terms.

- A term is either a variable or an application of a function symbol to a list of terms. (see Module **??**)
- Constraints consists of an interval and a set of so-called exclusive numbers.
- An atom is either an equality over terms, a disequality over terms, or a constraint for a term.

A partitioning `(v, d)` is defined as the conjunction of the variable equalities in `v` and variable disequalities in `d`, where `v` is of type `V.t` and `d` is of type `D.t`.

ICS supports the theories of equality over uninterpreted function symbols and a collection of interpreted theories including arithmetic, tuples, and bitvectors. For each function symbol in interpreted theories there is corresponding constructor function for building terms in a well-defined canonical form. In addition, for certain uninterpreted function symbols there are builtin rewrite rules. Solvers are only defined for interpreted theory.

This chapter describes the utility modules. The module *Tools* contained utility functions used in the implementation. The modules *Lexer* and *Parser* provide parsers for terms, equations, commands, etc. (we only give the interface for module *Lexer*). The module *Test* is a tiny toplevel to test the implementation. It allows the user to test the canonization and solver functions, and the algorithm.

6 Modules

6.1 Module sign

Interface for module Sign.mli

* Three-valued datatype for classifying real numbers into negative (*Neg*) numbers, the *Zero* number, and positive numbers (*Pos*).

type $t \;=\; Neg \mid Zero \mid Pos$

Module Sign.ml

* Three-valued datatype for classifying real numbers into negative (*Neg*) numbers, the *Zero* number, and positive numbers (*Pos*).

type $t \;=\; Neg \mid Zero \mid Pos$

6.2 Module three

Interface for module Three.mli

* Three-valued datatype.

There is an implicit partial ordering with $Yes < X$ and $No < X$.

type $t \;=$
$\mid Yes$
$\mid No$
$\mid X$

val $is\_sub \;:\; t \;\rightarrow\; t \;\rightarrow\; bool$
(** $is\_sub\ u\ v$* holds if either $u = v$ or $u < v$. *)

val $inter \;:\; t \;\rightarrow\; t \;\rightarrow\; t\ option$
(** $inter\ u\ v$* evaluates to $Some(w)$ if both $is\_sub\ w\ u$ and $is\_sub\ w\ v$ *)

```
val union : t → t → t
(* union u v evaluates to w if both is_sub u w and is_sub v w holds. *)
val is_disjoint : t → t → bool
```

Module Three.ml

```
type t =
  | Yes
  | No
  | X
let is_sub a b =
  match a, b with
    | _, X → true
    | (X | No), Yes → false
    | Yes, Yes → true
    | (X | Yes), No → false
    | No, No → true
let inter =
  let yes = Some(Yes) in (* avoid repetitive creation of constants. *)
  let no = Some(No) in
  let x = Some(X) in
  fun a b → match a, b with
    | No, X → no
    | Yes, X → yes
    | X, No → no
    | X, Yes → yes
    | No, No → no
    | X, X → x
    | Yes, Yes → yes
    | No, Yes → None
    | Yes, No → None
let union a b =
  match a, b with
    | _, X → X
    | X, _ → X
    | No, No → No
    | Yes, Yes → Yes
    | No, Yes → X
    | Yes, No → X
let is_disjoint a b =
  inter a b = None
```

6.3 Module gmp

Interface for module Gmp.mli

```
module Z2 : sig

  | *Singleton* of *Mpa.Q.t*
  | *Overlap* of α

6.6 Module hashcons

Interface for module Hashcons.mli

49. Module *Hashcons*: hashconsing over types with equality.

50. This module implements hashconsing of types with equalities by injecting elements a of this type into a record consisting of the node a itself, a unique integer tag, and a hash key for a.

The main advantage of hashconsing is that equality is reduced to a constant time operation. On the other hand, the penalty to pay is that every entity has to be hashconsed. Besides the time overhead there is also a space overhead for the storage of additional information in hashed elements and the use of global hash tables. These elements are never being garbage collected, since they are all kept in a hash table.

type α *hashed* $=$ $\{$
  hkey : *int*;
  tag : *int*;
  node : α

}

51. Equality for hashconsed entities reduces to identity, and can thus be performed in constant time.

val $(===)$: α *hashed* $\rightarrow$ α *hashed* $\rightarrow$ *bool*

52. Disequality a $=/=$ b is defined as $\neg(a$ $===$ $b)$.

val $(=/=)$: α *hashed* $\rightarrow$ α *hashed* $\rightarrow$ *bool*

The input signature of the functor *Hashcons.Make*. t is the type of the elements to be hashconsed. *equal* specifies the equality relation for hashconsing, and *hash* is a function for computing hash keys. Example: a suitable hashc function is often the generic hash function *hash*.

```
module type HashedType =
  sig
    type t
    val equal : t → t → bool
    val hash : t → int
  end

module type S =
  sig
    type key
```

53. The type of hash tables for hashconsing elements of type *key*.

```
    type t
```

54. *create* n creates a new, empty hash table, with initial size n. For best results, n should be on the order of the expected number of elements that will be in the table. The table grows as needed, so n is just an initial guess.

```
    val create : int → t
```

55. Empty a hash table.

```
    val clear : t → unit
```

56. Given a table t and a node a, *hashcons* t a returns a hashconsing record for a with a unique tag.

```
    val hashcons : t → key → key hashed
```

mem tbl x checks if x is bound in *tbl*.

```
    val mem : t → key → bool
```

57. *iter* f t applies f in turn to all hashconsed elements of t. The order in which the elements of t are presented to f is unspecified.

```
  val iter : (key hashed → unit) → t → unit
```

58. Prints on standard output some statistics for hash table t such as percentige of used entries, and maximum bucket length.

```
  val stat : t → unit
end
```

59. Functor building an implementation of the hashcons structure given a structure of signature *HashedType*.

```
module Make(H : HashedType) : (S with type key = H.t)
```

Module Hashcons.ml

```
type α hashed = {
  hkey : int;
  tag : int;
  node : α }

type α t = {
  mutable size : int; (* current size *)
  mutable data : α bucketlist array } (* the buckets *)

6.7 Module tools

Interface for module Tools.mli

60. The purpose of the *Tools* module is to provide some functions and types, which are used througout the code of ICS.

61. Procedures f without parameters can be registered as exit procedures by $add\_to\_exit\ f$. The registered exit procedures are then called by $do\_at\_exit()$. Exit procedures are usually used for displaying some statistics.

```
val add_at_exit : (unit → unit) → unit
val do_at_exit : unit → unit
```

62. $add\_to\_reset\ f$ registers f as a reset procedure, which are then called, one-by-one, by $do\_at\_reset()$.

val *add_at_reset* : $(unit \rightarrow unit) \rightarrow unit$
val *do_at_reset* : $unit \rightarrow unit$

63. *utime f a* returns not only the result of applying f to a but also the time required to compute the function.

val *utime* : $(\alpha \rightarrow \beta) \rightarrow \alpha \rightarrow \beta \times float$

64. *profile str f* profiles function f, and registers an exit function which outputs the number of calls of this function, and the total time spent in this function; the argument *str* is usually just the name of the function.

val *profile* : $string \rightarrow (\alpha \rightarrow \beta) \rightarrow (\alpha \rightarrow \beta)$

65. *dynamic_let* (x, v) f a simulated dynamic binding of value v to the global variable x in the call of f to a.

val *dynamic_let* : $\alpha\ ref \times \alpha \rightarrow (\beta \rightarrow \gamma) \rightarrow \beta \rightarrow \gamma$

Module Tools.ml

66. Functions to run at exit.

```
let at_exit_functions = ref []

let add_at_exit f =
  at_exit_functions := f :: !at_exit_functions

let do_at_exit () =
  List.iter (fun f -> f()) (List.rev !at_exit_functions)
```

67. Functions to run at reset.

```
let at_reset_functions = ref []

let add_at_reset f =
  at_reset_functions := f :: !at_reset_functions

let do_at_reset () =
  List.iter (fun f -> f()) (List.rev !at_reset_functions)
```

68. Timing functions.

```
open Unix

let utime f x =
  let u = (times()).tms_utime in
  let y = f x in
  let ut = (times()).tms_utime -. u in
  (y, ut)
```

```
let timers = ref [0.]
let profile str f =
  let timer = ref 0. in
  let calls = ref 0 in
  add_at_exit
    (fun () → Format.printf "%s: utime = %f  calls = %d\n@ " str !timer !calls);
  fun x →
    let start = (Unix.times()).tms_utime in
    let y = f x in
    let finish = (Unix.times()).tms_utime in
    timer := !timer +. (finish -. start);
    calls := !calls + 1;
    y
```

69. Simulate dynamic binding.

```
let dynamic_let (x, v) f a =
  let saved = !x in
    try
      let result = (x := v; f a) in
        x := saved;
        result
    with
      | exc →
          x := saved;
          raise exc
```

6.8 Module status

Interface for module Status.mli

```
type α t =

  Format.fprintf fmt "@[";
  pp1 fmt x;
  string fmt "␣|->␣";
  pp2 fmt a;
  Format.fprintf fmt "@]"

let map pp1 pp2 fmt =
  list ("[", ";␣", "]") (assign pp1 pp2) fmt

let tuple pp = list ("(", ",␣", ")") pp

let list pp = list ("[", ";␣", "]") pp

let solution pp = list (eqn pp)
```

73. Redirecting output.

```
let to_stdout pp = pp Format.std_formatter

let to_stderr pp = pp Format.err_formatter
```

```
let to_string pp x =
  pp Format.str_formatter x;
  Format.flush_str_formatter ()
```

6.10 Module exc

Interface for module Exc.mli

74. The module *Exc* defines the exceptions for indicating inconsistencies and validity.

exception *Inconsistent*

exception *Valid*

exception *Unsolved*

Module Exc.ml

exception *Inconsistent*

exception *Valid*

exception *Unsolved*

6.11 Module bitv

Interface for module Bitv.mli

75. $Id : bitv.mli, v1.12002/04/0301 : 13 : 04ruessExp$

76. Module Bitv. This module implements bit vectors, as an abstract datatype t. Since bit vectors are particular cases of arrays, this module provides the same operations as the module *Array*. It also provides bitwise operations. In the following, false stands for the bit 0 and true for the bit 1.

type t

77. Creation, access and assignment. (*Bitv.create n b*) creates a new bit vector of length n, initialized with b. (*Bitv.init n f*) returns a fresh vector of length n, with bit number i initialized to the result of $(f\ i)$. (*Bitv.set v n b*) sets the nth bit of v to the value b. (*Bitv.get v n*) returns the nth bit of v. *Bitv.length* returns the length (number of elements) of the given vector.

val *create* : $int \rightarrow bool \rightarrow t$

val *init* : $int \rightarrow (int \rightarrow bool) \rightarrow t$

val *set* : $t \rightarrow int \rightarrow bool \rightarrow unit$

val *get* : $t \rightarrow int \rightarrow bool$

val *length* : $t \rightarrow int$

78. *max_length* is the maximum length of a bit vector (System dependent).

val *max_length* : *int*

79. Copies and concatenations. (*Bitv.copy v*) returns a copy of v, that is, a fresh vector containing the same elements as v. (*Bitv.append v1 v2*) returns a fresh vector containing the concatenation of the vectors *v1* and *v2*. *Bitv.concat* is similar to *Bitv.append*, but catenates a list of vectors.

val *copy* : $t \rightarrow t$

val *append* : $t \rightarrow t \rightarrow t$

val *concat* : *t list* $\rightarrow t$

80. Sub-vectors and filling. (*Bitv.sub v start len*) returns a fresh vector of length *len*, containing the bits number *start* to $start + len - 1$ of vector v. Raise *Invalid_argument* `"Bitv.sub"` if *start* and *len* do not designate a valid subvector of v; that is, if $start < 0$, or $len < 0$, or $start + len > Bitv.length\ a$.

(*Bitv.fill v ofs len b*) modifies the vector v in place, storing b in elements number *ofs* to $ofs + len - 1$. Raise *Invalid_argument* `"Bitv.fill"` if *ofs* and *len* do not designate a valid subvector of v.

(*Bitv.blit v1 o1 v2 o2 len*) copies *len* elements from vector *v1*, starting at element number *o1*, to vector *v2*, starting at element number *o2*. It *does not work* correctly if *v1* and *v2* are the same vector with the source and destination chunks overlapping. Raise *Invalid_argument* `"Bitv.blit"` if *o1* and *len* do not designate a valid subvector of *v1*, or if *o2* and *len* do not designate a valid subvector of *v2*.

val *sub* : $t \rightarrow int \rightarrow int \rightarrow t$

val *fill* : $t \rightarrow int \rightarrow int \rightarrow bool \rightarrow unit$

val *blit* : $t \rightarrow int \rightarrow t \rightarrow int \rightarrow int \rightarrow unit$

81. Iterators. (*Bitv.iter f v*) applies function f in turn to all the elements of v. Given a function f, (*Bitv.map f v*) applies f to all the elements of v, and builds a vector with the results returned by f. *Bitv.iteri* and *Bitv.mapi* are similar to *Bitv.iter* and *Bitv.map* respectively, but the function is applied to the index of the element as first argument, and the element itself as second argument.

(*Bitv.fold_left f x v*) computes $f\ (...\ (f\ (f\ x\ (get\ v\ 0))\ (get\ v\ 1))\ ...)\ (get\ v\ (n-1))$, where n is the length of the vector v.

(*Bitv.fold_right f a x*) computes $f\ (get\ v\ 0)\ (f\ (get\ v\ 1)\ (\ ...\ (f\ (get\ v\ (n-1))\ x)\ ...))$, where n is the length of the vector v.

val *iter* : $(bool \rightarrow unit) \rightarrow t \rightarrow unit$

val *map* : $(bool \rightarrow bool) \rightarrow t \rightarrow t$

val *iteri* : $(int \rightarrow bool \rightarrow unit) \rightarrow t \rightarrow unit$
val *mapi* : $(int \rightarrow bool \rightarrow bool) \rightarrow t \rightarrow t$

val *fold_left* : $(\alpha \rightarrow bool \rightarrow \alpha) \rightarrow \alpha \rightarrow t \rightarrow \alpha$
val *fold_right* : $(bool \rightarrow \alpha \rightarrow \alpha) \rightarrow t \rightarrow \alpha \rightarrow \alpha$

82. Bitwise operations. *bwand*, *bwor* and *bwxor* implement logical and, or and exclusive or. They return fresh vectors and raise *Invalid_argument* `"Bitv.xxx"` if the two vectors do not have the same length (where `xxx` is the name of the function). *bwnot* implements the logical negation. It returns a fresh vector. *shiftl* and *shiftr* implement shifts. They return fresh vectors. *shiftl* moves bits from least to most significant, and *shiftr* from most to least significant (think lsl and lsr). *all_zeros* and *all_ones* respectively test for a vector only containing zeros and only containing ones.

val *bw_and* : $t \rightarrow t \rightarrow t$
val *bw_or* : $t \rightarrow t \rightarrow t$
val *bw_xor* : $t \rightarrow t \rightarrow t$
val *bw_not* : $t \rightarrow t$

val *shiftl* : $t \rightarrow int \rightarrow t$
val *shiftr* : $t \rightarrow int \rightarrow t$

val *all_zeros* : $t \rightarrow bool$
val *all_ones* : $t \rightarrow bool$

83. Conversions to and from strings. Least significant bit comes first.

val *to_string* : $t \rightarrow string$
val *from_string* : $string \rightarrow t$

84. Only if you know what you are doing...

val *unsafe_set* : $t \rightarrow int \rightarrow bool \rightarrow unit$
val *unsafe_get* : $t \rightarrow int \rightarrow bool$

Module Bitv.ml

85. $Id : bitv.ml, v 1.12002/04/0301 : 13 : 04 ruessExp$

86. Bit vectors. The interface and part of the code are borrowed from the *Array* module of the ocaml standard library (but things are simplified here since we can always initialize a bit vector). This module also provides bitwise operations.

87. We represent a bit vector by a vector of integers (field *bits*), and we keep the information of the size of the bit vector since it can not be found out with the size of the array (field *length*).

```
type t = {
  length : int;
  bits : int array }

let length v = v.length
```

88. Each element of the array is an integer containing *bpi* bits, where *bpi* is determined according to the machine word size. Since we do not use the sign bit, *bpi* is 30 on a 32-bits machine and 62 on a 64-bits machines. We maintain the following invariant: *The unused bits of the last integer are always zeros.* This is ensured by *create* and maintained in other functions using *normalize*. *bit_j*, *bit_not_j*, *low_mask* and *up_mask* are arrays used to extract and mask bits in a single integer.

```
let bpi = Sys.word_size - 2

let max_length = Sys.max_array_length * bpi

let bit_j = Array.init bpi (fun j -> 1 lsl j)
let bit_not_j = Array.init bpi (fun j -> max_int - bit_j.(j))

let low_mask = Array.create (succ bpi) 0
let _ =
  for i = 1 to bpi do low_mask.(i) <- low_mask.(i - 1) lor bit_j.(pred i) done

let keep_lowest_bits a j = a land low_mask.(j)

let high_mask = Array.init (succ bpi) (fun j -> low_mask.(j) lsl (bpi - j))

let keep_highest_bits a j = a land high_mask.(j)
```

89. Creating and normalizing a bit vector is easy: it is just a matter of taking care of the invariant. Copy is immediate.

```
let create n b =
  let initv = if b then max_int else 0 in
  let r = n mod bpi in
  if r = 0 then
    { length = n; bits = Array.create (n / bpi) initv }
  else begin
    let s = n / bpi in
    let b = Array.create (succ s) initv in
    b.(s) <- b.(s) land low_mask.(r);
    { length = n; bits = b }
  end

let normalize v =
  let r = v.length mod bpi in
  if r > 0 then
    let b = v.bits in
    let s = Array.length b in
    b.(s - 1) <- b.(s - 1) land low_mask.(r)
```

```
let copy v = { length = v.length; bits = Array.copy v.bits }
```

90. Access and assignment. The nth bit of a bit vector is the jth bit of the ith integer, where $i = n$ / *bpi* and $j = n$ mod *bpi*. Both i and j and computed by the function *pos*. Accessing a bit is testing whether the result of the corresponding mask operation is non-zero, and assigning it is done with a bitwiwe operation: an *or* with *bit_j* to set it, and an *and* with *bit_not_j* to unset it.

```
let pos n =
  let i = n / bpi and j = n mod bpi in
  if j < 0 then (i - 1, j + bpi) else (i,j)

let unsafe_get v n =
  let (i,j) = pos n in
  ((Array.unsafe_get v.bits i) land (Array.unsafe_get bit_j j)) > 0

let unsafe_set v n b =
  let (i,j) = pos n in
  if b then
    Array.unsafe_set v.bits i
      ((Array.unsafe_get v.bits i) lor (Array.unsafe_get bit_j j))
  else
    Array.unsafe_set v.bits i
      ((Array.unsafe_get v.bits i) land (Array.unsafe_get bit_not_j j))
```

91. The corresponding safe operations test the validiy of the access.

```
let get v n =
  if n < 0 ∨ n ≥ v.length then invalid_arg "Bitv.set";
  let (i,j) = pos n in
  ((Array.unsafe_get v.bits i) land (Array.unsafe_get bit_j j)) > 0

let set v n b =
  if n < 0 ∨ n ≥ v.length then invalid_arg "Bitv.set";
  let (i,j) = pos n in
  if b then
    Array.unsafe_set v.bits i
      ((Array.unsafe_get v.bits i) lor (Array.unsafe_get bit_j j))
  else
    Array.unsafe_set v.bits i
      ((Array.unsafe_get v.bits i) land (Array.unsafe_get bit_not_j j))
```

92. *init* is implemented naively using *unsafe_set*.

```
let init n f =
  let v = create n false in
  for i = 0 to pred n do
    unsafe_set v i (f i)
  done;
```

v

93. Handling bits by packets is the key for efficiency of functions *append*, *concat*, *sub* and *blit*. We start by a very general function *blit_bits a i m v n* which blits the bits i to $i+m-1$ of a native integer a onto the bit vector v at index n. It assumes that $i..i+m-1$ and $n..n+m-1$ are respectively valid subparts of a and v. It is optimized when the bits fit the lowest boundary of an integer (case $j \equiv 0$).

```
let blit_bits a i m v n =
  let (i', j) = pos n in
  if j ≡ 0 then
    Array.unsafe_set v i'
      ((keep_lowest_bits (a lsr i) m) lor
       (keep_highest_bits (Array.unsafe_get v i') (bpi - m)))
  else
    let d = m + j - bpi in
    if d > 0 then begin
      Array.unsafe_set v i'
        (((keep_lowest_bits (a lsr i) (bpi - j)) lsl j) lor
         (keep_lowest_bits (Array.unsafe_get v i') j));
      Array.unsafe_set v (succ i')
        ((keep_lowest_bits (a lsr (i + bpi - j)) d) lor
         (keep_highest_bits (Array.unsafe_get v (succ i')) (bpi - d)))
    end else
      Array.unsafe_set v i'
        (((keep_lowest_bits (a lsr i) m) lsl j) lor
         ((Array.unsafe_get v i') land (low_mask.(j) lor high_mask.(-d))))
```

94. *blit_int* implements *blit_bits* in the particular case when $i = 0$ and $m = bpi$ i.e. when we blit all the bits of a.

```
let blit_int a v n =
  let (i, j) = pos n in
  if j ≡ 0 then
    Array.unsafe_set v i a
  else begin
    Array.unsafe_set v i
      ( (keep_lowest_bits (Array.unsafe_get v i) j) lor
        ((keep_lowest_bits a (bpi - j)) lsl j));
    Array.unsafe_set v (succ i)
      ((keep_highest_bits (Array.unsafe_get v (succ i)) (bpi - j)) lor
       (a lsr (bpi - j)))
  end
```

95. When blitting a subpart of a bit vector into another bit vector, there are two possible cases: (1) all the bits are contained in a single integer of the first bit vector, and a single

call to *blit_bits* is the only thing to do, or (2) the source bits overlap on several integers of the source array, and then we do a loop of *blit_int*, with two calls to *blit_bits* for the two bounds.

```
let unsafe_blit v1 ofs1 v2 ofs2 len =
  let (bi, bj) = pos ofs1 in
  let (ei, ej) = pos (ofs1 + len - 1) in
  if bi ≡ ei then
    blit_bits (Array.unsafe_get v1 bi) bj len v2 ofs2
  else begin
    blit_bits (Array.unsafe_get v1 bi) bj (bpi - bj) v2 ofs2;
    let n = ref (ofs2 + bpi - bj) in
    for i = succ bi to pred ei do
      blit_int (Array.unsafe_get v1 i) v2 !n;
      n := !n + bpi
    done;
    blit_bits (Array.unsafe_get v1 ei) 0 (succ ej) v2 !n
  end
```

```
let blit v1 ofs1 v2 ofs2 len =
  if len < 0 ∨ ofs1 < 0 ∨ ofs1 + len > v1.length
               ∨ ofs2 < 0 ∨ ofs2 + len > v2.length
  then invalid_arg "Bitv.blit";
  unsafe_blit v1.bits ofs1 v2.bits ofs2 len
```

96. Extracting the subvector $ofs..ofs + len - 1$ of v is just creating a new vector of length *len* and blitting the subvector of v inside.

```
let sub v ofs len =
  if ofs < 0 ∨ len < 0 ∨ ofs + len > v.length then invalid_arg "Bitv.sub";
  let r = create len false in
  unsafe_blit v.bits ofs r.bits 0 len;
  r
```

97. The concatenation of two bit vectors *v1* and *v2* is obtained by creating a vector for the result and blitting inside the two vectors. *v1* is copied directly.

```
let append v1 v2 =
  let l1 = v1.length
  and l2 = v2.length in
  let r = create (l1 + l2) false in
  let b1 = v1.bits in
  let b2 = v2.bits in
  let b = r.bits in
  for i = 0 to Array.length b1 - 1 do
    Array.unsafe_set b i (Array.unsafe_get b1 i)
  done;
```

```
  unsafe_blit b2 0 b l1 l2;
  r
```

98. The concatenation of a list of bit vectors is obtained by iterating *unsafe_blit*.

```
let concat vl =
  let size = List.fold_left (fun sz v → sz + v.length) 0 vl in
  let res = create size false in
  let b = res.bits in
  let pos = ref 0 in
  List.iter
    (fun v →
       let n = v.length in
       unsafe_blit v.bits 0 b !pos n;
       pos := !pos + n)
    vl;
  res
```

99. Filling is a particular case of blitting with a source made of all ones or all zeros. Thus we instanciate *unsafe_blit*, with 0 and *max_int*.

```
let blit_zeros v ofs len =
  let (bi, bj) = pos ofs in
  let (ei, ej) = pos (ofs + len − 1) in
  if bi ≡ ei then
    blit_bits 0 bj len v ofs
  else begin
    blit_bits 0 bj (bpi − bj) v ofs;
    let n = ref (ofs + bpi − bj) in
    for i = succ bi to pred ei do
      blit_int 0 v !n;
      n := !n + bpi
    done;
    blit_bits 0 0 (succ ej) v !n
  end

let blit_ones v ofs len =
  let (bi, bj) = pos ofs in
  let (ei, ej) = pos (ofs + len − 1) in
  if bi ≡ ei then
    blit_bits max_int bj len v ofs
  else begin
    blit_bits max_int bj (bpi − bj) v ofs;
    let n = ref (ofs + bpi − bj) in
    for i = succ bi to pred ei do
      blit_int max_int v !n;
      n := !n + bpi
```

```
    done;
    blit_bits max_int 0 (succ ej) v !n
  end
let fill v ofs len b =
  if ofs < 0 ∨ len < 0 ∨ ofs + len > v.length then invalid_arg "Bitv.fill";
  if b then blit_ones v.bits ofs len else blit_zeros v.bits ofs len
```

100. All the iterators are implemented as for traditional arrays, using *unsafe_get*. For *iter* and *map*, we do not precompute (*f* true) and (*f* false) since *f* is likely to have side-effects.

```
let iter f v =
  for i = 0 to v.length − 1 do f (unsafe_get v i) done
let map f v =
  let l = v.length in
  let r = create l false in
  for i = 0 to l − 1 do
    unsafe_set r i (f (unsafe_get v i))
  done;
  r
let iteri f v =
  for i = 0 to v.length − 1 do f i (unsafe_get v i) done
let mapi f v =
  let l = v.length in
  let r = create l false in
  for i = 0 to l − 1 do
    unsafe_set r i (f i (unsafe_get v i))
  done;
  r
let fold_left f x v =
  let r = ref x in
  for i = 0 to v.length − 1 do
    r := f !r (unsafe_get v i)
  done;
  !r
let fold_right f v x =
  let r = ref x in
  for i = v.length − 1 downto 0 do
    r := f (unsafe_get v i) !r
  done;
  !r
```

101. Bitwise operations. It is straigthforward, since bitwise operations can be realized by the corresponding bitwise operations over integers. However, one has to take care of normalizing the result of *bwnot* which introduces ones in highest significant positions.

```
let bw_and v1 v2 =
  let l = v1.length in
  if l ≠ v2.length then invalid_arg "Bitv.bw_and";
  let b1 = v1.bits
  and b2 = v2.bits in
  let n = Array.length b1 in
  let a = Array.create n 0 in
  for i = 0 to n - 1 do
    a.(i) ← b1.(i) land b2.(i)
  done;
  { length = l; bits = a }

let bw_or v1 v2 =
  let l = v1.length in
  if l ≠ v2.length then invalid_arg "Bitv.bw_or";
  let b1 = v1.bits
  and b2 = v2.bits in
  let n = Array.length b1 in
  let a = Array.create n 0 in
  for i = 0 to n - 1 do
    a.(i) ← b1.(i) lor b2.(i)
  done;
  { length = l; bits = a }

let bw_xor v1 v2 =
  let l = v1.length in
  if l ≠ v2.length then invalid_arg "Bitv.bw_xor";
  let b1 = v1.bits
  and b2 = v2.bits in
  let n = Array.length b1 in
  let a = Array.create n 0 in
  for i = 0 to n - 1 do
    a.(i) ← b1.(i) lxor b2.(i)
  done;
  { length = l; bits = a }

let bw_not v =
  let b = v.bits in
  let n = Array.length b in
  let a = Array.create n 0 in
  for i = 0 to n - 1 do
    a.(i) ← max_int land (lnot b.(i))
  done;
  let r = { length = v.length; bits = a } in
  normalize r;
```

```
  r
```

102. Shift operations. It is easy to reuse *unsafe_blit*, although it is probably slightly less efficient than a ad-hoc piece of code.

```
let rec shiftl v d =
  if d ≡ 0 then
    copy v
  else if d < 0 then
    shiftr v (−d)
  else begin
    let n = v.length in
    let r = create n false in
    if d < n then unsafe_blit v.bits 0 r.bits d (n − d);
    r
  end

and shiftr v d =
  if d ≡ 0 then
    copy v
  else if d < 0 then
    shiftl v (−d)
  else begin
    let n = v.length in
    let r = create n false in
    if d < n then unsafe_blit v.bits d r.bits 0 (n − d);
    r
  end
```

103. Testing for all zeros and all ones.

```
let all_zeros v =
  let b = v.bits in
  let n = Array.length b in
  let rec test i =
    (i ≡ n) ∨ ((Array.unsafe_get b i ≡ 0) ∧ test (succ i))
  in
  test 0

let all_ones v =
  let b = v.bits in
  let n = Array.length b in
  let rec test i =
    if i ≡ n − 1 then
      let m = v.length mod bpi in
      (Array.unsafe_get b i) ≡ (if m ≡ 0 then max_int else low_mask.(m))
    else
```

```
      ((Array.unsafe_get b i) ≡ max_int) ∧ test (succ i)
  in
  test 0
```

104. Conversions to and from strings.

```
let to_string v =
  let n = v.length in
  let s = String.make n '0' in
  for i = 0 to n − 1 do
    if unsafe_get v i then s.[i] ← '1'
  done;
  s

let from_string s =
  let n = String.length s in
  let v = create n false in
  for i = 0 to n − 1 do
    let c = String.unsafe_get s i in
    if c = '1' then
      unsafe_set v i true
    else
      if c ≠ '0' then invalid_arg "Bitv.from_string"
  done;
  v
```

6.12 Module extq

Interface for module Extq.mli

105. Module *Extq*: Arithmetic operations on the rationals extended with positive and negative infinity.

```
type extq =
  | Inject of Mpa.Q.t
  | Posinf
  | Neginf

and t
```

106. Constructors.

```
val of_q : Mpa.Q.t → t
val posinf : t
val neginf : t
```

107. Destructor.

val *destruct* : $t \rightarrow$ *extq*

108. Is the extended real a real, and translating to a rational if possible.

val *is_q* : $t \rightarrow$ *bool*
val *to_q* : $t \rightarrow$ *Mpa.Q.t option*

val *is_z* : $t \rightarrow$ *bool*
val *to_z* : $t \rightarrow$ *Mpa.Z.t option*

109. Test if argument is an integer.

val *is_int* : $t \rightarrow$ *bool*

110. Printing an extended rational.

val *pp* : *Format.formatter* $\rightarrow$ $t \rightarrow$ *unit*

111. Derived constructors.

val *zero* : t
val *is_zero* : $t \rightarrow$ *bool*

112. Equality on extended reals.

val *eq* : $t \rightarrow t \rightarrow$ *bool*

113. Extended reals are ordered as among the reals, if both are real. Moreover, - *inf* $<$ c $<$ + *inf* for any real c.

val *lt* : $t \rightarrow t \rightarrow$ *bool*
val *le* : $t \rightarrow t \rightarrow$ *bool*

114. Comparison.

val *cmp* : $t \rightarrow t \rightarrow$ *Mpa.Q.cmp*

115. Minimum and maximum.

val *min* : $t \rightarrow t \rightarrow t$
val *max* : $t \rightarrow t \rightarrow t$

116. Sign computation.

val *sign* : $t \rightarrow$ *Sign.t*

let is_z x =
  match x with
    | Inject(q) when Mpa.Q.is_integer q -> true
    | _ -> false
let to_z x =
  assert(is_z x);
  match x with
    | Inject(q) -> Some(Mpa.Q.to_z q)
    | _ -> None
let of_q = inject
let pp fmt x =
  match x with
```

```
    | Inject q → Q.pp fmt q
    | Posinf → Format.fprintf fmt "inf"
    | Neginf → Format.fprintf fmt "-inf"
```

120. Test if argument is an integer.

```
let is_int x =
  match x with
    | Inject q → Q.is_integer q
    | _ → false
```

121. Equality is just pointer comparison for hash-consing.

```
let eq x y =
  match x, y with
    | Inject(q), Inject(p) → Q.equal q p
    | Posinf, Posinf → true
    | Neginf, Neginf → true
    | _ → false
```

122. Ordering relation.

```
let lt x y =
  match x with
    | Inject q →
        (match y with
           | Inject p → Q.lt q p
           | Posinf → true
           | Neginf → false)
    | Neginf → true
    | Posinf → false

let le x y =
  eq x y ∨ lt x y
```

123. Minimum and maximum.

```
let min x y = if lt x y then x else y

let max x y = if lt x y then y else x
```

124. Comparisons.

```
let cmp x y =
  match x, y with
    | Inject u, Inject v → Q.cmp u v
    | Inject _, Posinf → Q.Less
    | Inject _, Neginf → Q.Greater
    | Neginf, Neginf → Q.Equal
    | Neginf, _ → Q.Less
```

```
    | Posinf, Posinf → Q.Equal
    | Posinf, _ → Q.Greater
```

125. Sign computation.

```
let sign x =
  match x with
    | Inject q → Q.sign q
    | Posinf → Sign.Pos
    | Neginf → Sign.Neg
```

126. Arithmetic operations

```

6.13 Module dom

Interface for module Dom.mli

127. Module *Dom*: Various subdomains of numbers. *Real* denotes the domain of the real numbers, *Int* all integers. There is a reflexive subdomain ordering $<$ with $Int < Real$

type $t = Int \mid Nonint \mid Real$

128. Equality on domains.

val $eq : t \to t \to bool$

129. *union d1 d2* returns d iff the domain of d is the union of the domains of *d1* and *d2*.

val $union : t \to t \to t$

130. *inter d1 d2* returns d iff the domain of d is the intersection of the domains of *d1* and *d2*.

exception *Empty*

val $inter : t \to t \to t$

sub d1 d2 tests if the domain of *d1* is a subdomain of *d2*.

val $sub : t \to t \to bool$

131. *cmp d1 d2* returns *Sub* (*Equal*, *Disjoint*, *Super*) if the domain of *d1* is a subset (is equal, is disjoint, is a superset) of *d2*.

val $cmp : t \to t \to unit\ Binrel.t$

132. *of_q u* returns *Int* if the rational u is integer and *Real*

```
val of_q : Mpa.Q.t → t
```

133. *mem q d* tests if *q* is a member of *d*.

```
val mem : Mpa.Q.t → t → bool
```

134. Pretty-printing

```
val pp : Format.formatter → t → unit
```

Module Dom.ml

135.
```
type t = Int | Nonint | Real

let eq d1 d2 = (d1 = d2)
```

136. Union of two domains

```
let union d1 d2 =
  match d1, d2 with
    | Int, Int → Int
    | Nonint, Nonint → Nonint
    | _ → Real
```

137. Intersection of two domains

```
exception Empty

let inter d1 d2 =

6.14 Module endpoint

Interface for module Endpoint.mli

140. Module *Endpoint*: datatype for endpoints of intervals.

```
type t = Extq.t × bool
```

141. Constructor.

```
val make : Extq.t × bool → t
```

142. Accessors.

val *destruct* : $t \rightarrow Extq.t \times bool$

val *value* : $t \rightarrow Extq.t$
val *kind* : $t \rightarrow bool$

143. Test if endpoint is a rational or integer.

val *is_q* : $t \rightarrow bool$

val *is_z* : $t \rightarrow bool$

144. Get value of a rational/integer endpoint.

val *q_of* : $t \rightarrow Mpa.Q.t$

val *z_of* : $t \rightarrow Mpa.Z.t$

145. Strictness/Nonstrictness test.

val *is_strict* : $t \rightarrow bool$
val *is_nonstrict* : $t \rightarrow bool$

146. Extreme endpoints

val *neginf* : t
val *posinf* : t

val *strict* : $Mpa.Q.t \rightarrow t$
val *nonstrict* : $Mpa.Q.t \rightarrow t$

val *eq* : $t \rightarrow t \rightarrow bool$

Module Endpoint.ml

147. type $t = Extq.t \times bool$

148. Constructor.

let *make* $e = e$

149. Accessors.

let *destruct* $e = e$

let *value* $e = fst\ e$
let *kind* $e = snd\ e$

150. Extreme endpoints

let *neginf* $= (Extq.neginf, \mathsf{false})$
let *posinf* $= (Extq.posinf, \mathsf{false})$

```
let strict u = (Extq.of_q u, false)
let nonstrict u = (Extq.of_q u, true)
```

151. Equality.

```
let eq (a, alpha) (b, beta) =
  match Extq.destruct a, Extq.destruct b with
    | Extq.Inject u, Extq.Inject v → alpha = beta ∧ Mpa.Q.equal u v
    | Extq.Posinf, Extq.Posinf → true
    | Extq.Neginf, Extq.Neginf → true
    | _ → false
```

152. Test if endpoint is a rational.

```
let is_q (a, _) = Extq.is_q a
let is_z (a, _) = Extq.is_z a
```

153. Get value of a rational endpoint.

```
let q_of (a, _) =
  assert(Extq.is_q a);
  match Extq.to_q a with
    | Some(q) → q
    | _ → assert false
let z_of (a, _) =
  assert(Extq.is_z a);
  match Extq.to_z a with
    | Some(q) → q
    | _ → assert false
```

154. Strictness/Nonstrictness test.

```
let is_strict (_, alpha) = ¬ alpha
let is_nonstrict (_, alpha) = alpha
```

6.15 Module interval

Interface for module Interval.mli

155. Module *Interval*: Real intervals with rational endpoints (including infinity).

```
type t
```

make d $(a, alpha)$ $(b, beta)$ constructs a general, interval with rational endpoints a and b (including negative and positive infinity) and two bits of information *alpha* and *beta*, with *alpha* (resp. *beta*) specifying whether a (resp. b) belongs to the interval. Each interval

denotates a set of reals (or integers), denoted by $D(i)$. $D(make\ d\ (a,\mathsf{true})\ (b,\mathsf{true}))$ equals the closed interval $\{x\ \mathsf{in}\ d \mid a \leq x \leq b\}$, $D(make\ d\ (a,\mathsf{true})\ (b,\mathsf{false}))$ is the right-open interval $\{x\ \mathsf{in}\ d \mid a \leq x < b\}$, $D(make\ d\ (a,\mathsf{false})\ (b,\ \mathsf{true}))$ denotes the left-open interval $\{x\ \mathsf{in}\ d \mid a < x \leq b\}$, and $D(make\ d\ (a,\mathsf{false})\ (b,\mathsf{false}))$ denotes the open interval $\{x\ \mathsf{in}\ d \mid a < x < b\}$.

val *make* : $Dom.t \times Endpoint.t \times Endpoint.t \rightarrow t$

156. The accessor *destructure* i returns the endpoint information (d, lo, hi) for an interval i with denotation $D(make\ d\ lo\ hi)$. *lo* i returns the lower bound in the form $(a, alpha)$ and *hi* i the upper bound in the form $(b,\ beta)$.

val *destructure* : $t \rightarrow Dom.t \times Endpoint.t \times Endpoint.t$

val *dom* : $t \rightarrow Dom.t$
val *lo* : $t \rightarrow Endpoint.t$
val *hi* : $t \rightarrow Endpoint.t$

157. Derived constructors.

val *mk_zero* : t
val *mk_empty* : t
val *mk_real* : t
val *mk_int* : t
val *mk_nonint* : t
val *mk_singleton* : $Mpa.Q.t \rightarrow t$

158. *is_singleton* i returns the single value for an interval whose denotation is a singleton set over the reals.

val *d_singleton* : $t \rightarrow Mpa.Q.t\ option$
val *is_empty* : $t \rightarrow bool$
val *is_full* : $t \rightarrow bool$

159. *rational_endpoints* i returns the pair of rational endpoints.

val *rational_endpoints* : $t \rightarrow (Mpa.Q.t \times Mpa.Q.t)\ option$

160. *mem* q i tests if the rational q is a member of the interval i.

val *mem* : $Mpa.Q.t \rightarrow t \rightarrow bool$

161. Equality *eq* i j on intervals i, j holds if and only if they denote the same set of numbers. In particular, two empty intervals are always identified to be equal.

val *eq* : $t \rightarrow t \rightarrow bool$

162. Union and intersection of two intervals. It is the case that the denotation of *union* i j (resp. *inter* i j) is the union (resp. intersection) of the denotations of i and j.

val *union* : $t \rightarrow t \rightarrow t$

val *inter* : $t \rightarrow t \rightarrow t$

163. Interval arithmetic. Let i, j be two intervals with denotations $D(i)$ and $D(j)$. Then, $D(add\ i\ j)$ is $D(i) + D(j)$, $D(sub\ i\ j)$ is $D(i) - D(j)$, $D(mult\ i\ j)$ is $D(i) \times D(j)$, and $D(div\ i\ j)$ consists of the set of rationals $\{z | \exists x \in D(i), y \in D(j)$ such that $y/ = 0$, $z = x/y\}$.

val *add* : $t \rightarrow t \rightarrow t$
val *subtract* : $t \rightarrow t \rightarrow t$
val *multq* : $Mpa.Q.t \rightarrow t \rightarrow t$
val *mult* : $t \rightarrow t \rightarrow t$
val *expt* : $int \rightarrow t \rightarrow t$
val *div* : $t \rightarrow t \rightarrow t$

164. Comparisons.

val *cmp* : $t \rightarrow t \rightarrow t\ Binrel.t$

val *sub* : $t \rightarrow t \rightarrow bool$

val *disjoint* : $t \rightarrow t \rightarrow bool$

165. Printing an interval.

val *pp* : $Format.formatter \rightarrow t \rightarrow unit$

Module Interval.ml

166. General real intervals are represented by their endpoints a and b and two bits of information *alpha* and *beta*, with *alpha* (resp. *beta*) specifying whether a (resp. b) belongs to the interval. More formally. (a, b,true,true) denotes the closed interval $\{ x$ in $R \mid u \leq x \leq v\}$, (a, b,true,false) denotes the right-open interval $\{ x$ in $R \mid u \leq x < v\}$, (a, b,false,true) denotes the left-open interval $\{ x$ in $R \mid u < x \leq v\}$, and (a, b,false,false) denotes the open interval $\{x$ in $R \mid u < x < v\}$.

type $t = tnode$

and $tnode = \{$
  dom : $Dom.t$;
  lo : $Endpoint.t$;
  hi : $Endpoint.t$
}

167. Accessors.

```
let tuple = Product(Tuple)
let car = Product(Proj(0, 2))
let cdr = Product(Proj(1, 2))
```

6.20 Module term

Interface for module Term.mli

231. Terms are the basic data structures of ICS.

232. Terms. A term is either a variable $Var(s)$, where the name s is a string, an application $App(f, l)$ of a 'function symbol' to a list of arguments, an update expression $Update(a, i, v)$, or a term interpreted in one of the theories of linear arithmetic *Arith*, propositional logic, *Prop*, propositional sets *Set*, tuples *Tuple*, or bitvectors *Bv*. By definition, all entitities of type t are hash-consed. Therefore, equality tests between terms can be done in constant time using the equality $===$ from the module *Hashcons*.

Arithmetic terms are either numerals of the form $Num(q)$, n-ary addition $Add(l)$, linear multiplication $Multq(q, a)$, nonlinear multiplication $Mult(l)$, or division. Arithmetic terms built up solely from *Num*, *Add*, and *Multq* are considered to be interpreted, since *Mult* and *Div* are considered to be uninterpreted, in general. However, certain simplification rules for these uninterpreted function symbols are built-in.

Propositional terms are either *False*, *True*, or conditionals $Ite(a, b, c)$. Other propositional connectives can be encoded using these constructor.

A tuple term is either a tuple $Tup(l)$ or the i-th projection $Proj(i, n, \_)$ from an n-tuple.

Set of terms are implemented using Patricia trees. Operations on these sets are described below in the submodule *Set*.

```
type t =
  | Var of Var.t
  | App of Sym.t × t list
```

233. Constructing and destructing terms

```
val mk_var : Name.t → t
val mk_const : Sym.t → t
val mk_app : Sym.t → t list → t

val mk_fresh_var : Name.t → int option → t
val is_fresh_var : t → bool
val name_of : t → Name.t

val destruct : t → Sym.t × t list

val sym_of : t → Sym.t
val args_of : t → t list
```

234. Equality of terms.

```
val eq : t → t → bool

val eql : t list → t list → bool

val cmp : t → t → int
```

val $(<<<) : t \to t \to bool$

val $orient : t \times t \to t \times t$

val $max : t \to t \to t$
val $min : t \to t \to t$

235. Test if term is a constant.

val $is\_const : t \to bool$

val $is\_var : t \to bool$
val $is\_app : t \to bool$

val $to\_var : t \to Var.t$

val $is\_interp\_const : t \to bool$

val $is\_equal : t \to t \to Three.t$

236. Fold operator on terms.

val $fold : (t \to \alpha \to \alpha) \to t \to \alpha \to \alpha$

237. Iteration operator on terms.

val $iter : (t \to unit) \to t \to unit$

238. Predicate holds for all subterms.

val $for\_all : (t \to bool) \to t \to bool$

239. *subterm a b* holds if a is a subterm of b.

val $subterm : t \to t \to bool$

240. *occurs x a* holds if term x occurs in a.

val $occurs : t \to t \to bool$

241. Mapping over list of terms. Avoids unnecessary consing.

val $mapl : (t \to t) \to t\ list \to t\ list$

242. Association lists for terms.

val $assq : t \to (t \times \alpha)\ list \to \alpha$

243. Printer.

val $pretty : bool\ ref$

val $pp : Format.formatter \to t \to unit$

val $to\_string : t \to string$

244. Pretty-printing pairs as equalities/disequalities/constraints.

```
val pp_equal : (t × t) Pretty.printer
val pp_diseq : (t × t) Pretty.printer
val pp_in : (t × Cnstrnt.t) Pretty.printer
```

245. Sets and maps of terms.

```
type trm = t
module Set : (Set.S with type elt = trm)
module Map : (Map.S with type key = trm)
```

246. Return set of variables.

```
val vars_of : t → Set.t
```

Module Term.ml

247. Terms.

```
type t =
  | Var of Var.t
  | App of Sym.t × t list
let rec eq a b =
  match a, b with
    | Var(x), Var(y) →
        Var.eq x y
    | App(f, l), App(g, m) →
        Sym.eq f g ∧ eql l m
    | _ →
        false
and eql al bl =
  try List.for_all2 eq al bl with Invalid_argument _ → false
```

248. Constructors.

```
let mk_var x = Var(Var.mk_var x)
let mk_const f = App(f, [])
let mk_app f l = App(f, l)
let mk_fresh_var x k = Var(Var.mk_fresh x k)
let is_fresh_var = function
  | Var(x) → Var.is_fresh x
  | _ → false
```

249. Recognizers.

```
let is_var = function Var _ → true | _ → false
let is_app = function App _ → true | _ → false
let is_const = function App(_,[]) → true | _ → false
```

250. Destructors.

```
let to_var = function
  | Var(x) → x
  | _ → assert false

let name_of a =
  assert(is_var a);
  match a with Var(x) → Var.name_of x | _ → assert false

let destruct a =
  assert(is_app a);
  match a with App(f,l) → (f,l) | _ → assert false

let sym_of a =
  assert(is_app a);
  match a with App(f,_) → f | _ → assert false

let args_of a =
  assert(is_app a);
  match a with App(_,l) → l | _ → assert false
```

251. Structural comparison.

```
let rec cmp a b =
  match a, b with
    | Var _, App _ → 1
    | App _, Var _ → -1
    | Var(x), Var(y) → Var.cmp x y
    | App(f, l), App(g, m) →
        let c1 = Sym.cmp f g in
        if c1 ≠ 0 then c1 else cmpl l m

and cmpl l m =
  let rec loop c l m =
    match l, m with
      | [], [] → c
      | [], _ → -1
      | _, [] → 1
      | x :: xl, y :: yl →
          if c ≠ 0 then loop c xl yl else loop (cmp x y) xl yl
  in
  loop 0 l m
```

```
let (<<<) a b = (cmp a b ≤ 0)
```

252. *cmp* forces function applications to be smaller than constants. Thus, *cmp* makes sure that e.g. $f(x) = c$ is added in this order. Otherwise, the term ordering is arbitrary and we use *Term.cmp* for ordering all the other cases.

```
let orient ((a, b) as e) =
  if cmp a b ≥ 0 then e else (b, a)

let min a b =
  if a <<< b then a else b

let max a b =
  if a <<< b then b else a
```

253. Some recognizers.

```
let is_interp_const = function
  | App((Arith _ | Bv _ | Product _), []) → true
  | _ → false

let is_interp = function
  | App((Arith _ | Bv _ | Product _), _) → true
  | _ → false

let is_uninterpreted = function
  | App(Uninterp _, _) → true
  | _ → false

let is_equal a b =
  if eq a b then
    Three.Yes
  else match a, b with (* constants from within a theory are *)
    | App((Arith _ as c), []), App((Arith _ as d), []) (* assumed to interpreted differently
*)
        when ¬(Sym.eq c d) → Three.No
    | App((Bv _ as c), []), App((Bv _ as d), [])
        when ¬(Sym.eq c d) → Three.No
    | _ →
        Three.X
```

254. Mapping over list of terms. Avoids unnecessary consing.

```
let rec mapl f l =
  match l with
    | [] → []
    | a :: l1 →
        let a' = f a and l1' = mapl f l1 in
        if eq a' a ∧ l1 ≡ l1' then l else a' :: l1'
```

255. Association lists for terms.

```
let rec assq a = function
  | [] → raise Not_found
  | (x, y) :: xl → if eq a x then y else assq a xl
```

256. Iteration over terms.

```
let rec fold f a acc =
  match a with
    | Var _ → f a acc
    | App(_, l) → f a (List.fold_right (fold f) l acc)

let rec iter f a =

6.23 Module arith

Interface for module Arith.mli

262. Module *Arith*: Constructors, recognizers, and accessors for arithmetic terms. Solvers for rational and integer arithmetic. Processing arithmetic equalities.

263. *is_interp a* holds iff *a* is a inear arithmetic terms; that is, *a* is either a numeral (constructed with *num*, see below), a linear multiplication (*multq*), or an addition (*add*, *add2*).

val *is_interp* : *Term.t* → *bool*

264. *fold f a e* applies *f* at uninterpreted positions of *a* and accumulates the results starting with *e*.

val *fold* : (*Term.t* → α → α) → *Term.t* → α → α

265. Some normalization functions.

val *poly_of* : *Term.t* → *Mpa.Q.t* × *Term.t list*
val *of_poly* : *Mpa.Q.t* → *Term.t list* → *Term.t*

val *mono_of* : *Term.t* → *Mpa.Q.t* × *Term.t*
val *of_mono* : *Mpa.Q.t* → *Term.t* → *Term.t*

val *monomials* : *Term.t* → *Term.t list*

266. Constructors for building up arithmetic terms. Arithmetic terms are always in polynomial normal form. That is, they either represent a rational *num q*, a power product *x* of the form *x1* × ... ∗ *xn*, for $n \geq 1$, where the *xi* are uninterpreted, a monomial *q* × *x*, where the coefficient *q* is a non-zero rational, and *x* a power product, or a (flattened) sum of monomials in ascending order, with respect to the *Term.cmp* comparison, from left-to-right.

num q builds a rational numeral with value *q*, *zero* just abbreviates *num* `'0'`, and *one* abbreviates *num* `'1'`. *add2* (*a*, *b*) sums up two terms, *add l* sums the list *l* of terms, and *incr a* increments its argument term. *sub* (*a*, *b*) is subtraction, while *mult2* and *mult* construct terms for multiplication, and *div* divides two terms. In addition, these constructors implement a number of simplifications such as *div x* (*mult x x*) = *div* (*num* `'1'`) *x*.

val *mk_num* : *Mpa.Q.t* → *Term.t*
val *mk_zero* : *Term.t*

val *mk_one* : *Term.t*
val *mk_two* : *Term.t*

val *mk_add* : *Term.t* → *Term.t* → *Term.t*
val *mk_addl* : *Term.t list* → *Term.t*
val *mk_incr* : *Term.t* → *Term.t*
val *mk_sub* : *Term.t* → *Term.t* → *Term.t*
val *mk_neg* : *Term.t* → *Term.t*
val *mk_multq* : *Mpa.Q.t* → *Term.t* → *Term.t*

267. Recognizers.

val *is_num* : *Term.t* → *bool*

val *is_zero* : *Term.t* → *bool*
val *is_one* : *Term.t* → *bool*
val *is_q* : *Mpa.Q.t* → *Term.t* → *bool*

268. Destructors.

val *d_num* : *Term.t* → *Q.t option*
val *d_add* : *Term.t* → *Term.t list option*
val *d_multq* : *Term.t* → (*Q.t* × *Term.t*) *option*

269. Given an arithmetic operation *Num*(*q*), *Multq*(*q*), *Add*, *Mult*, or *Div* as declared in *term.mli*, *sigma op l* builds a normalized application by applying the corresponding constructor to the list l of terms. Hereby, it is assumed that l is empty for *Num*(*q*), the singleton list for *Multq*(*q*), a list of length two for *Div*, and lists of length greater or equal to two for both *Add* and *Mult*.

val *sigma* : *Sym.arith* → *Term.t list* → *Term.t*

270. Given a substitution s and a term a, *norm s a* replaces uninterpreted occurrences x in a with term y, if there is a binding $x \mid-> y$ in s. The resulting term is in polynomial normal form. Thus, *norm* can be thought of as the the composition of applying substitution s to a followed by sigmatizing each arithmetic subterm by the function *sigma* above.

val *map* : (*Term.t* → *Term.t*) → *Term.t* → *Term.t*

271. *solve x* (a, b) solves the equation $a = b$ over the rationals. If this equation is inconsistent, then it raises *Exc.Inconsistent*. In case the equation holds trivially it returns the empty solution *None*. Otherwise, it returns the solution $x = t$ as *Some*(x, t), where x is one of the power products of either a or b, and x does not occur in t. In addition, t is in normalized form. There are usually several choices for the power product x to solve for, and *qsolve* chooses to solve for the largest power product according to the term ordering $\ll$.

val *solve_for* : (*Term.t* → *bool*) → *Fact.equal* → *Fact.equal option*

val *solve* : *Fact.equal* → *Fact.equal option*

272. Abstract interpretation in the domain of constraints. Given a context f, which associates uninterpreted subterms of a with constraints, *cnstrnt f a* recurses over the interpreted

structure of a and accumulates constraints by calling f at uninterpreted positions and abstractly interpreting the interpreted arithmetic operators in the domain of constraints. May raise the exception *Not_found*, when some uninterpreted subterm of a is not in the domain of f.

val *tau* : (*Term.t* → *Cnstrnt.t*) → *Sym.arith* → *Term.t list* → *Cnstrnt.t*

Module Arith.ml

273. Theory-specific recognizers

```
let is_interp a =
  match a with
    | App(Arith _, _) → true
    | _ → false
```

            Cnstrnt.multq q (c x)
        | Add, [x; y] →
            Cnstrnt.add (c x) (c y)
        | Add, _ →
            Cnstrnt.addl (List.map c al)
        | _ →
            Cnstrnt.mk_real)
  with
      Not_found → Cnstrnt.mk_real
```

6.24 Module tuple

Interface for module Tuple.mli

287. Module *Tuple*: canonizer and solver for the theory of tuples.

The signature of this theory consists of the nary function symbol *Product* for constructing tuples and of the family of unary function symbols $Proj(i,\ n)$, for integers $0 \leq i < n$, for projecting the i-th component (starting with 0 and addressing in increasing order from left to right).

The theory of tuples is given as the initial algebra generated by the axioms

288. *is_interp a* holds iff a is a projection of the form $Proj(i,\ n)(x)$ or a tuple term $Product(xl)$. Terms for which *is_interp* is false are considered to be uninterpreted.

```
val is_interp : Term.t → bool
```

289. If the argument list l is of length 1, then this term is returned. Otherwise, *tuple l* constructs the corresponding tuple term.

val *mk_tuple* : *Term.t list* → *Term.t*

290. *proj i n a* is the constructor for the family of i-th projections from n-tuples, where i is any integer value between 0 and $n-1$. This constructor simplifies *proj i n* (*tuple* \ *list*{*a_0*; ...; *a_n*−1}) to *a_i*.

val *mk_proj* : *int* → *int* → *Term.t* → *Term.t*

291. *sigma op l* applies the function symbol *op* from the tuple theory to the list *l* of terms. For the function symbol $Proj(i, n)$ and the list a, it simply applies the constructor *proj i n a*, and for *Tuple* and it applies *tuple l*. All other inputs result in a run-time error.

val *sigma* : *Sym.product* → *Term.t list* → *Term.t*

292. *fold f a e* applies f at uninterpreted positions of a and accumulates the results starting with e.

val *fold* : (*Term.t* → α → α) → *Term.t* → α → α

293. *map f a* applies f to all top-level uninterpreted subterms of a, and rebuilds the interpreted parts in order.

val *map* : (*Term.t* → *Term.t*) → *Term.t* → *Term.t*

294. *solve* (a, b) returns a solved form for the equation $a = b$. If this equation is inconsistent, then the exception *Exc.Inconsistent* is raised. Otherwise, the solved form $(x1, e1), ..., (xn, en)$ is returned, where *xi* are uninterpreted in the tuple theory and the *ei* are canonized. The *ei* may also contain fresh variables.

val *solve* : *Fact.equal* → *Fact.equal list*

Module Tuple.ml

295.
```
let is_interp = function
  | App(Product _, _) → true
  | _ → false

```

6.26 Module bitvector

Interface for module Bitvector.mli

312. Module *Bv*: Constructors, recognizers, and accessors for bitvector terms, and a solver for equations over bitvectors. Bitvectors of width n, where n is a natural number, are arrays of bits with positions 0 through $n-1$ in increasing order from left-to-right.

313. *is_interp a* holds iff the top-level function symbol of a is interpreted in the theory of bitvectors (see also module *Sym*.

```
val is_interp : Term.t -> bool
```

314. Computes the width of a bitvector term.

```
val width : Term.t -> int option
```

315. *iter f a* applies f for all toplevel subterms of a which are not interpreted in the theory of bitvectors.

```
val iter : (Term.t -> unit) -> Term.t -> unit
```

316. *fold f a e* applies f at uninterpreted positions of a and accumulates the results starting with e.

```
val fold : (Term.t -> 'a -> 'a) -> Term.t -> 'a -> 'a
```

317. *mk_const c* is the constructor for building constant bitvectors, in which all bits are known to be either 0 or 1. *mk_zero n* is just defined to be the constant zero bitvector of length n, *mk_one n* is the constant one bitvector of length n, and *mk_eps* is the constant bitvector of length 0.

```
val mk_eps : Term.t
val mk_one : int -> Term.t
val mk_zero : int -> Term.t
val mk_const : Bitv.t -> Term.t
```

318. *is_zero a* holds iff all bits in a are 0.

```
val is_zero : Term.t -> bool
```

319. *is_one a* holds iff all bits in a are 1.

val *is_one* : *Term.t* → *bool*

320. *mk_conc n m b1 b2* concatenates a bitvector *b1* of width *n* and a bitvector *b2* of width *m*. *mk_conc* terms are built up in a right-associative way, argument bitvectors of length 0 are ignored, constant argument bitvectors are combined into the corresponding concatenated constant bitvector, and concatentations of extractions such as *mk_sub x i j* and *mk_sub x* $(j+1)$ *k* are merged to *mk_sub x i k*.

val *mk_conc* : *int* → *int* → *Term.t* → *Term.t* → *Term.t*

321. *mk_sub n i j x* returns the representation of the bitvector for the contiguous extraction of the $j - i + 1$ bits *i* through *j* in the bitvector *x* of length *n*. It is assumed that $0 \leq i, j < n$. If $j < i$ then the empty bitvector *mk_eps* is returned, and if $i = j$ then the result is a bitvector of width 1. Simplifications include extraction of bitvector terms, *mk_sub* distributes over concatenation and bitwise operators, and successive extractions are merged.

val *mk_sub* : *int* → *int* → *int* → *Term.t* → *Term.t*

322. *mk_bitwise n a b c* builds bitvector BDDs of width *n*. Bitvector BDDs are a canonical form for bitwise conditionals of width *n*, and they are similar to a binary decision diagram (BDD) in that *mk_bitwise n a b c* reduces to *c* when *is_zero a* holds, it reduces to *b* when *is_one a* holds, and to *b* if *b* is syntactically equal to *c*. Furthermore the conditional structure is reduced in that there are no identical substructures, and the conditional parts are ordered from top to bottom (this ordering is fixed but unspecified). Since bitwise operations distribute over concatenation and extraction, all terms in a bitvector BDD are either bitvector constants, uninterpreted terms, or a (single) extraction from an uninterpreted term.

val *mk_bitwise* : *int* → *Term.t* → *Term.t* → *Term.t* → *Term.t*

323. Derived bitwise operators for bitwise conjunction (*mk_bwconj*), disjunction (*mk_bwconj*), negation (*mk_bwconj*), implication (*mk_bwconj*), and equivalence (*mk_bwconj*).

val *mk_bwconj* : *int* → *Term.t* → *Term.t* → *Term.t*
val *mk_bwdisj* : *int* → *Term.t* → *Term.t* → *Term.t*
val *mk_bwneg* : *int* → *Term.t* → *Term.t*
val *mk_bwimp* : *int* → *Term.t* → *Term.t* → *Term.t*
val *mk_bwiff* : *int* → *Term.t* → *Term.t* → *Term.t*

324. Given a bitvector symbol *f* (see module *Sym*) and a list *l* of arguments, *sigma f l* returns a concatenation normal form (CNF) of the application $'f(l)'$. A CNF is either a simple bitvector or a right-associative concatenation of simple bitvectors, and a simple bitvector is either an uninterpreted term, a bitvector constant, an extraction, or a bitvector BDD (see above). All the simplifications for *mk_sub*, *mk_conc*, *mk_bitwise* are applied.

val *sigma* : *Sym.bv* → *Term.t list* → *Term.t*

325. *map f a* applies *f* to all top-level uninterpreted subterms of *a*, and rebuilds the interpreted parts in order. It can be thought of as replacing every toplevel uninterpreted *a*

with $'f(a)'$ if *Not_found* is not raised by applying a, and with a otherwise, followed by a sigmatization of all interpreted parts using *mk_sigma*.

val *map* : $(Term.t \rightarrow Term.t) \rightarrow Term.t \rightarrow Term.t$

326. *solve* b either fails, in which case b is unsatisfiable in the given bitvector theory or it returns a list of equations $\backslash list\{(x1, e1); ...(xn, en)\}$ such that xi is a non bitvector term, all the xi are pairwise disjoint, none of the xi occurs in any of the terms ej, and, viewed as a conjunction of equivalences, the result is equivalent (in the theory of bitvectors) with b. The terms ei may contain fresh bitvector constants.

val *solve* : *Fact.equal* $\rightarrow$ *Fact.equal list*

      end
```

408. Return disequalities for x.

```
let disequalities s x =
  Term.Set.fold
    (fun y acc →
       (Fact.mk_diseq x y None) :: acc)
    (deq s x)
    []
```

6.37 Module v

Interface for module V.mli

409. Module V: Representation of equivalence classes of variables.

type t

410. *partition* s returns a partitioning of the set of variables in the form of a map with a domain consisting of canonical representatives and the corresponding equivalence class in the codomain. It does only list non-singleton equivalence classes.

val *partition* : $t \rightarrow$ *Term.Set.t Term.Map.t*

411. *find* s x returns the canonical representative of x with respect ot the partitioning of the variables in s. In addition, *find*$'$ performs dynamic path compression as a side effect.

val *find* : $t \rightarrow$ *Term.t* $\rightarrow$ *Term.t*

val *find*$'$: $t \rightarrow$ *Term.t* $\rightarrow$ $t \times$ *Term.t*

val *justification* : $t \rightarrow$ *Term.t* $\rightarrow$ *Term.t* $\times$ *Fact.justification option*

val *equality* : $t \rightarrow$ *Term.t* $\rightarrow$ *Fact.equal*

412. The set of changed x in domain.

val *changed* : *Term.Set.t ref*

413. Set of removable variables.

val *removable* : *Term.Set.t ref*

414. Equality test.

val *eq* : $t \rightarrow t \rightarrow$ *bool*

415. *is_equal* s x y holds if and only if x and y are in the same equivalence class modulo s.

val *is_equal* : $t \rightarrow$ *Term.t* $\rightarrow$ *Term.t* $\rightarrow$ *bool*

416. The empty context.

val *empty* : t

417. Adding a variable equality $x = y$ to a context s.

val *merge* : *Fact.equal* $\rightarrow t \rightarrow t$

418. *restrict* x s removes occurrences of x from s. Should only be called for x in *removable* s.

```
val restrict : Term.t → t → t
```

419. Pretty-printing.

```
val pp : t Pretty.printer
```

420. Folding over the members of a specific equivalence class.

```
val fold : t → (Term.t → α → α) → Term.t → α → α
```

421. Iterate over the extension of an equivalence class.

```
val iter : t → (Term.t → unit) → Term.t → unit
```

422. *exists s p x* holds if *p y* holds for some *y* congruent to *x* modulo *s*.

```
val exists : t → (Term.t → bool) → Term.t → bool
```

423. *for_all s p x* holds if *p y* holds for all *y* congruent to *x* modulo *s*.

```
val for_all : t → (Term.t → bool) → Term.t → bool
```

424. *choose s p x* chooses a *y* which is congruent to *x* modulo *s* which satisfies *p*. If there is no such *y*, the exception *Not_found* is raised.

```
val choose : t → (Term.t → α option) → Term.t → α
```

      x;
    raise Not_found
  with
      Found → !result
```

435. Set of canonical representatives with non-trivial equivalence classes. These are the variables occurring in the codomain of *find* which are not themselves in the domain of *find*.

```
let canrepr s =
  Map.fold
    (fun _ (y, _) acc →
       if Map.mem y s.find then
```

```
        acc
      else
        Set.add y acc)
  s.find
  Set.empty
```

436. Representation of the equivalence classes as a map with the canonical representatives as domain and the corresponding extensions in the codomain. The following is not terribly efficient.

```
let partition s =
  Set.fold
    (fun x →
       Map.add x (ext s x))
    (canrepr s)
    Map.empty
```

437. Pretty-printing.

```
let pp fmt s =
  if ¬(is_empty s) then
    let m = partition s in
    let l = Map.fold (fun x ys acc → (x, Set.elements ys) :: acc) m [] in
    Pretty.string fmt "\nv:";
    Pretty.map Term.pp (Pretty.set Term.pp) fmt l
```

6.38 Module c

Interface for module C.mli

438. type t

val $cnstrnts : t \to (Cnstrnt.t \times Fact.justification\ option)\ Var.Map.t$

val $to\_list : t \to (Var.t \times Cnstrnt.t)\ list$

val $apply : t \to Term.t \to Cnstrnt.t$

val $to\_fact : t \to Term.t \to Fact.cnstrnt$

val $mem : Term.t \to t \to bool$

439. Empty constraint map.

val $empty : t$

val $eq : t \to t \to bool$

440. Add a new constraint.

val *add* : *Fact.cnstrnt* → *t* → *t*

441. Changed.

val *changed* : *Set.t ref*

442. Merge a variable equality $x = y$ in the constraint map by adding x in ij for the canonical variable x, where x in i, y in j are in the constraint map and ij is the intersection of i and j, and by removing the constraint for y. In case, ij is a singleton constraint with element q, an equality $x = q$ is generated. Singleton constraints are always retained in the constraint map in order to keep the invariant that the best available constraint are always associated with canonical variables.

val *merge* : *Fact.equal* → *t* → *t*

443. Propagate disequalities to the constraint part. The following is not complete and should be extended to all finite constraints, but the disequality sets might become rather large then.

val *diseq* : *Fact.diseq* → *t* → *t*

444. Split.

val *split* : *t* → *Atom.Set.t*

445. Pretty-printing.

val *pp* : *t Pretty.printer*

```

450. Merge a variable equality $x = y$ in the constraint map by adding x in ij for the canonical variable x, where x in i, y in j are in the constraint map and ij is the intersection of i and j, and by removing the constraint for y. In case, ij is a singleton constraint with element q, an equality $x = q$ is generated. Singleton constraints are always retained in the constraint map in order to keep the invariant that the best available constraint are always associated with canonical variables.

```
let merge e s =
  Trace.msg "c1" "Equal" e Fact.pp_equal;
  let (x, y, prf) = Fact.d_equal e in (* prf |- x = y *)
  try
    let (i, prf1) = justification s x in (* prf1 |- x in i *)
    let s' = restrict x s in

6.40 Module partition

Interface for module Partition.mli

455. Module *Partition*: A partition consists of a

- set of variable equalities $x = y$,
- a set of variable disequalities $x \neq y$,
- and a set of variable constraints x in i,

where i is an arithmetic constraint of type *Cnstrnt.t*.

```
type t
```

456. Accessors.

```
val v_of : t -> V.t
val d_of : t -> D.t
val c_of : t -> C.t
```

457. The *empty* partition.

```
val empty : t
```

458. *v s x* returns the canonical representative of the equivalence class in the partitioning *s* containing the variable *x*.

val v : t → *Term.t* → *Term.t*

459. c s x returns, for a canonical variable x, an associatiatede arithmetic constraint, if there is one. Otherwise, *Not_found* is raised.

val c : t → *Term.t* → *Cnstrnt.t*

460. *update_v* s v updates the v part of the partitioning s if it is different from $s.v$. Similarly, *update_d* and *update_c* update the disequality part and the constraint part, respectively.

val *update_v* : t → $V.t$ → t
val *update_d* : t → $D.t$ → t
val *update_c* : t → $C.t$ → t

461. *copy* p does a shallow copying of p.

val *copy* : t → t

462. *is_int* s a tests if the constraint *cnstrnt* s a is included in *Cnstrnt.mk_int*.

val *is_int* : t → *Term.t* → *bool*

463. *deq* s x returns the set of all variable y disequal to x as stored in the variable disequality part d of the partitioning s. Disequalities as obtained from the constraint part c are not necessarily included.

val *deq* : t → *Term.t* → *Term.Set.t*

464. Pretty-printing of a partitioning.

val *pp* : t *Pretty.printer*

465. *is_equal* s x y for variables x, y returns *Three.Yes* if x and y belong to the same equivalence class modulo s, that is, if v s x and v s y are equal. The result is *Three.No* if x is in *deq* y, y is in *deq* x, or x in i and y in j are constraints in s and i, j are disjoint. Otherwise, *Three.X* is returned.

val *is_equal* : t → *Term.t* → *Term.t* → *Three.t*

merge e s adds a new variable equality e of the form $x = y$ into the partition s. If x is already equal to y modulo s, then s is unchanged; if x and y are disequal, then the exception *Exc.Inconsistent* is raised; otherwise, the equality $x = y$ is added to s to obtain s' such that v s' x is identical to v s' y.

val *merge* : *Fact.equal* → t → t

466. *remove* s removes all internal variables which are not canonical.

val *restrict* : *Term.Set.t* → t → t

467. *add* c s adds a constraint of the form x in i to the constraint part c of the partition s. May raise *Exc.Inconsistent* if the resulting constraint for x is the empty constraint (see *C.add*).

val *add* : *Fact.cnstrnt* → *t* → *t*

468. *diseq d s* adds a disequality of the form $x \neq y$ to s. If $x = y$ is already known in s, that is, if *is_equal s x y* yields *Three.Yes*, then an exception *Exc.Inconsistent* is raised; if *is_equal s x y* equals *Three.No* the result is unchanged; otherwise, $x \neq y$ is added using *D.add*.

val *diseq* : *Fact.diseq* → *t* → *t*

469. Return stored facts.

val *equality* : *t* → *Term.t* → *Fact.equal*
val *disequalities* : *t* → *Term.t* → *Fact.diseq list*
val *cnstrnt* : *t* → *Term.t* → *Fact.cnstrnt*

470. *eq s t* holds if the respective equality, disequality, and constraint parts are identical, that is, stored in the same memory location.

val *eq* : *t* → *t* → *bool*

471. Management of changed variables.

```
module Changed : sig
  val reset : unit → unit
  val save : unit → Term.Set.t × Term.Set.t × Term.Set.t
  val restore : Term.Set.t × Term.Set.t × Term.Set.t → unit
  val stable : unit → bool
end
```

Module Partition.ml

472. Equalities and disequalities over variables and constraints on variables

```

```

479. Test if states are unchanged.

```
let eq s t =
  V.eq s.v t.v ∧
  D.eq s.d t.d ∧
  C.eq s.c t.c
```

480. Equality test.

```
let is_equal s x y =
  let x' = v s x in
  let y' = v s y in
  if Term.eq x' y' then
    Three.Yes
  else if D.is_diseq s.d x' y' then
    Three.No
  else
    try
      let i = C.apply s.c x in
      let j = C.apply s.c y in
      if Cnstrnt.is_disjoint i j then
```

```
        Three.No
      else
        Three.X
    with
        Not_found → Three.X
```

481. Test for integerness.

```
let is_int s x =
  try
    let i = C.apply s.c x in
    Cnstrnt.dom_of i = Dom.Int
  with
      Not_found → false
```

Merge a variable equality.

```
let merge e s =
  let (x, y, _) = Fact.d_equal e in
  match is_equal s x y with
    | Three.Yes → s
    | Three.No → raise Exc.Inconsistent
    | Three.X →
        Trace.msg "p" "Merge" e Fact.pp_equal;
        let v' = V.merge e s.v in
        let d' = D.merge e s.d in
        let c' = C.merge e s.c in
          update_v (update_d (update_c s c') d') v'
```

482. Add a constraint.

```
let add c s =
  let c' = C.add c s.c in
    if C.eq s.c c' then s else
      begin
        Trace.msg "p" "Add" c Fact.pp_cnstrnt;
          update_c s c'
      end
```

483. Add a disequality.

```
let diseq d s =
  let (x, y, _) = Fact.d_diseq d in
  match is_equal s x y with
    | Three.Yes →
        raise Exc.Inconsistent
    | Three.No →
        s
```

```
    | Three.X →
        let d' = D.add d s.d in
        let c' = C.diseq d s.c in
          Trace.msg "p" "Diseq" d Fact.pp_diseq;
          update_d (update_c s c') d'
let restrict xs s =
  let v' = Set.fold V.restrict xs s.v in
    update_v s v'
```

484. Stored facts.

```
let equality p = V.equality p.v
let disequalities p = D.disequalities p.d
let cnstrnt p = C.to_fact p.c
```

485. Management of changed sets.

```
module Changed = struct
  let reset () =
    V.changed := Set.empty;
    D.changed := Set.empty;
    C.changed := Set.empty
  let save () = (!V.changed, !D.changed, !C.changed)

    C.changed := c
  let stable () =
    !V.changed = Set.empty ∧
    !D.changed = Set.empty ∧
    !C.changed = Set.empty
end
```

6.41 Module solution

Interface for module Solution.mli

486. Module *Solution*: abstract datatype for representing and manipulating conjunctions of equations $x = a$, where x is a variable and a is a non-variable term. As an invariant, solution sets s are kept in functional form, that is, if $x = a$ and $x = b$ in s, then a is identical with b. In addition, solution sets are injective, that is, $x = a$ and $y = a$ are not in a solution set for $x \neq y$.

type t

487. *to_list* s returns a list of pairs $(x,\ a)$, where x is a variable and a a term for the equalities $x = a$ in the solution set s.

val *to_list* : $t \to (Term.t \times Term.t)$ *list*

488. Pretty-printing of solution sets.

val *pp* : *Th.t* $\to$ t *Pretty.printer*

489. *fold* f s e applies f x a to all $x = a$ in the solution set s in an unspecified order and accumulates the result.

val *fold* : $(Term.t \to Term.t \times Fact.justification\ option \to \alpha \to \alpha) \to t \to \alpha \to \alpha$

490. *apply* s x returns b if $x = b$ is in s, and raises *Not_found* otherwise.

val *apply* : $t \to Term.t \to Term.t$

find s x returns b if $x = b$ is in s, and x otherwise. For non-variable argument a, *find* s a always returns a.

val *find* : $t \to Term.t \to Term.t$

491. *justification* s x returns $(b,\ j)$ if $x = b$ is in s with justification j. Raises *Not_found* if there is no such justification.

val *justification* : $t \to Term.t \to Term.t \times Fact.justification\ option$

val *equality* : $t \to Term.t \to Fact.equal$

492. *inv* s b returns x if $x = b$ is in s; otherwise *Not_found* is raised.

val *inv* : $t \to Term.t \to Term.t$

493. *mem* s x holds iff $x = b$ is in s.

val *mem* : $t \to Term.t \to bool$

494. *occurs* s x holds if either *mem* s x or if x is a variable in some b where $y = b$ is in s.

val *occurs* : $t \to Term.t \to bool$

495. *use* s x returns all y such that $y = a$ in s and x is a variable in *Term.vars* a.

val *use* : $t \to Term.t \to Term.Set.t$

496. The *empty* solution set, which does not contain any equality.

val *empty* : t

497. *is_empty* s holds iff s does not contain any equalities.

val *is_empty* : $t \rightarrow$ *bool*

498. *eq* s t tests if the solution sets s and t are identical in the sense that the sets of equalities are stored at the same memory location.

val *eq* : $t \rightarrow t \rightarrow$ *bool*

499. *restrict* s x removes equalities $x = a$ from s.

val *restrict* : *Th.t* $\rightarrow$ *Term.t* $\rightarrow t \rightarrow t$

500. *union* $(x,\ b)$ s adds an equality $x = b$ to s, possibly removing an equality $x = b'$ in s.

val *union* : *Th.t* $\rightarrow$ *Fact.equal* $\rightarrow t \rightarrow t$

501. *name* s a returns the variable x if there is an equation $x = a$ in s. Otherwise, it creates a fresh variiable x' and installs a solution $x' = a$ in s.

val *name* : *Th.t* $\rightarrow$ *Term.t* $\times t \rightarrow$ *Term.t* $\times t$

502. *fuse norm* $(p,\ s)$ r propagates the equalities in r on the right-hand side of equalities in s. The return value $(p',\ s')$ consists vi of an extension of the partition p with newly generated variable equalities and a modified solution set s', which is obtained by transforming every $x = b$ in s to $x = norm(r)(b)$. Here, $norm(r)(b)$ replaces occurrences of z in b with a if $z = a$ is in r and normalizes the result according to the *norm* argument function. If $norm(r)(b)$ reduces to a variable, say y, then the variable equality $x = y$ is added to the partition p. This may trigger an exception *Not_found*, if the disequality $x \neq y$ can be deduced from the partition p. This equality is also propagated in the resulting s' in that every occurrence of x is replaced by y. In case $norm(r)(b)$ results in a non-variable b', the equality $x = b'$ is added if there is no $y = b'$ already in the solution set. If there is such a y, then the equality $x = y$ is added to the partitioning p and only one of $x = b'$, $y = b'$ is retained in the resulting solution set.

val *fuse* : *Th.t* $\rightarrow$ *Partition.t* $\times t \rightarrow$ *Fact.equal list* $\rightarrow$ *Partition.t* $\times t$

503. *compose norm* (p, s) r is a *fuse* step followed by extending (and possibly overwriting $x = ...$) the resulting s' with all $x = b$, for b a non-variable term, in sl. If b is a variable, then it is added to v' and ch' is extended accordingly.

val *compose* : *Th.t* $\rightarrow$ *Partition.t* $\times t \rightarrow$ *Fact.equal list* $\rightarrow$ *Partition.t* $\times t$

504. Every modification or addition of an equality $x = a$ to a solution set s— using *union*, *fuse*, or *compose*—has the side-effect of adding x to the set of changed variables in s. This set can be obtained by *changed* s. *reset* s resets the set of changed variables in s to the empty set.

module *Changed* : sig

6.42 Module context

Interface for module Context.mli

517. Module *Context*: The logical context of the decision procedures.

518. A logical context is given by a tuple $(ctxt, u, i, d)$ where

- *ctxt* is the set of atoms used for building up this logical context.
- u consists of a set of equalities $x = y$ over terms x, y which are either uninterpreted or interpreted constants (see module U).
- i is the context of interpreted solution sets (see module Th).
- d stores the known disequalities over uninterpreted terms (see module D).

```
type t

val ctxt_of : t → Atom.Set.t
val p_of : t → Partition.t
val eqs_of : t → Th.t → Solution.t
val upper_of : t → int

val v_of : t → V.t
val d_of : t → D.t
val c_of : t → C.t

val empty : t
```

519. Pretty-printing the context of a state.

```
val pp : t Pretty.printer
```

520. Identity test on contexts.

val *eq* : $t \to t \to$ *bool*

521. For an term a which is either uninterpreted or an interpreted constant, *type_of* s a returns the most refined type as obtained from both static information encoded in the arity of uninterpreted function symbols (see module *Sym*) and the constraint context *c_of* s.

val *cnstrnt* : $t \to$ *Term.t* $\to$ *Cnstrnt.t*

val *is_equal* : $t \to$ *Term.t* $\to$ *Term.t* $\to$ *Three.t*

522. Variable partitioning.

val *v* : $t \to$ *Term.t* $\to$ *Term.t*
val *d* : $t \to$ *Term.t* $\to$ *Term.Set.t*
val *c* : $t \to$ *Term.t* $\to$ *Cnstrnt.t*

523. Fold over an equivalence class.

val *fold* : $t \to (\mathit{Term.t} \to \alpha \to \alpha) \to \mathit{Term.t} \to \alpha \to \alpha$

524. *lookup* s a returns, if possible, a canonical variable equal to a.

val *lookup* : $t \to$ *Term.t* $\to$ *Term.t*

525. *choose* s p x returns z if for some y in the equivalence class of x p y yields *Some*(z). If there is not such y, *Not_found* is raised.

val *choose* : $t \to (\mathit{Term.t} \to \alpha\ \mathit{option}) \to \mathit{Term.t} \to \alpha$

526. Parameterized operators

val *mem* : *Th.t* $\to$ $t \to$ *Term.t* $\to$ *bool*
val *apply* : *Th.t* $\to$ $t \to$ *Term.t* $\to$ *Term.t*
val *find* : *Th.t* $\to$ $t \to$ *Term.t* $\to$ *Term.t*
val *inv* : *Th.t* $\to$ $t \to$ *Term.t* $\to$ *Term.t*
val *use* : *Th.t* $\to$ $t \to$ *Term.t* $\to$ *Term.Set.t*
val *equality* : *Th.t* $\to$ $t \to$ *Term.t* $\to$ *Fact.equal*

527. *sigma* normal form.

val *sigma* : $t \to$ *Sym.t* $\to$ *Term.t list* $\to$ *Term.t*

528. *solve* i s (a, b) applies solver for theory i on equality $a = b$.

val *solve* : *Th.t* $\to$ $t \to$ *Fact.equal* $\to$ *Fact.equal list*

529. Updates.

val *extend* : *Atom.t* $\to$ $t \to$ t

val *union* : *Th.t* $\to$ *Fact.equal* $\to$ $t \to$ t

val *restrict* : *Th.t* $\to$ *Term.t* $\to$ $t \to$ t

```
val fuse : Th.t → Fact.equal → t → t
val compose : Th.t → Fact.equal → t → t
val update : Partition.t → t → t
val name : Th.t → t × Term.t → t × Term.t
```

530. List all constraints with finite extension.

```
val split : t → Atom.Set.t
module Changed : sig
  type t
  val in_v : t → Term.Set.t
  val in_d : t → Term.Set.t
  val in_c : t → Term.Set.t
  val in_eqs : Th.t → t → Term.Set.t
  val reset : unit → unit
  val save : unit → t
  val restore : t → unit
  val stable : unit → bool
  val pp : t Pretty.printer
end
```

531. Update rules work on the following global variables together with the index for creating new variables. Within a *protect* environment, updates are performed destructively. Global variables are not protected!

```
val protect : (t → t) → t → t
```

Module Context.ml

532. Decision procedure state.

```
type t = {

  let e' = Fact.mk_equal x' y' None in
    union i e' s

let update p s = (s.p ← p; s)
```

Lookup terms on rhs of solution sets.

```
let lookup s a =
  match a with
    | Var _ →
        v s a
    | App(f, _) →
        let i = Th.of_sym f in
          try
            let x = inv i s a in
              v s x
          with
              Not_found → a
```

544. List all constraints with finite extension.

```
let split s = C.split (c_of s)
```

545. Administration of changed sets. For each of component v, d, c of the partition there is such a set stored in respective global variables $V.changed$, $D.changed$, and $C.changed$. Here, we define the change sets for the theory-specific solution sets. In addition, functions for saving, resetting, and restoring are provided.

```
module Changed = struct
  type t = Term.Set.t × Term.Set.t × Term.Set.t × Term.Set.t Array.arr
  let reset () =
    Partition.Changed.reset ();
    Solution.Changed.reset ()
  let save () =
    let (v, d, c) = Partition.Changed.save () in
    let e = Solution.Changed.save () in
      (v, d, c, e)
  let restore (v, d, c, e) =
    Partition.Changed.restore (v, d, c);
    Solution.Changed.restore e
  let stable () =
    Partition.Changed.stable () ∧
```

```
    Solution.Changed.stable ()

  let in_v (v, _, _, _) = v
  let in_d (_, d, _, _) = d
  let in_c (_, _, c, _) = c
  let in_eqs i (_, _, _, e) = Array.get e i

  let pp fmt (v, d, c, e) =
    let ppset str xs =
      if ¬(Set.is_empty xs) then
        begin
          Format.fprintf fmt "\n%s: " str;
          Pretty.set Term.pp fmt (Set.elements xs)
        end
    in
      ppset "v" v; ppset "d" d; ppset "c" c;
      Array.iter (fun i → ppset (Th.to_string i)) e

end
```

546. Update rules work on the following global variables together with the index for creating new variables. Within a *protect* environment, updates are performed destructively. Global variables are protected!

```
let protect f s =
  let k' = !Var.k in
  let r' = !V.removable in
  let ch' = Changed.save () in
    try
      Var.k := s.upper;
      Changed.reset ();
      V.removable := Term.Set.empty;
      let s' = f (copy s) in
        s'.upper ← !Var.k;
        Var.k := k';
        V.removable := r';
        Changed.restore ch';
        s'

6.44 Module arrays

Interface for module Arrays.mli

555. *propagate* e $(p,\ u)$ possibly deduces new equalities from the variable equality e of the form $x = y$. If both $z1 = select(u,\ j1)$ and $z2 = update(a2, i2, k2)$ are in the solution

set u, and if and $u = z2$, $x = i2$, $y = j1$ are known to be true in the partitioning p, then the equality $z1 = k2$ is added to p.

val *propagate* : *Fact.equal* → *Context.t* → *Context.t*

556. *diseq* d $(p,\ u)$ propagates a disequality d of the form $i \neq j$. If $z1 = select(upd,\ j')$, $z2 = update(a, i', x)$ are equalities in u and if $i = i'$, $j = j'$, $upd = z2$ are equalities in the partitioning p, then the variable equality $z1 = z3$ is added to p. Either $z3 = select(a, j)$ is already in u or $z3$ is generated and the equality $z3 = select(a, j)$ is added to u.

val *diseq* : *Fact.diseq* → *Context.t* → *Context.t*

Module Arrays.ml

557. From the equality $x = y$ and the facts $z1 = select(upd1, j1)$, $z2 = update(a2, i2, k2)$ in s and $upd1 \equiv z2 \bmod s$, $x \equiv i2 \bmod s$, $y \equiv j1 \bmod s$ deduce that $z1 = k2$.

```
let rec propagate e s =
  Trace.msg "rule" "Array(=)" e Fact.pp_equal;
  let (x, y, prf) = Fact.d_equal e in
    propagate1 (x, y, prf)
      (propagate1 (y, x, prf) s)
and propagate1 (x, y, prf) s =
    Set.fold
      (fun z1 s1 →
         match apply Th.arr s1 z1 with
           | App(Arrays(Select), [upd1; j1])
               when is_equal s1 y j1 = Three.Yes →
               fold s1
                 (fun z2 s2 →

  outchannel = Format.std_formatter;
  eot = "";
  counter = 0
}
let s = init ()
```

622. Initialize.

```
let initialize pp eot inch outch =
  Term.pretty := pp;
  s.eot ← eot;
  s.inchannel ← inch;
  s.outchannel ← outch
```

623. Accessors to components of global state.

```
let current () = s.current
let symtab () = s.symtab
let eot () = s.eot
let inchannel () = s.inchannel
let outchannel () = s.outchannel
```

624. Adding to symbol table

```
let def n a =
  let e = Symtab.Def(a) in
  s.symtab ← Symtab.add n e s.symtab

let sgn n a =
  let e = Symtab.Arity(a) in
  s.symtab ← Symtab.add n e s.symtab

let typ n c =
  let e = Symtab.Type(c) in
  s.symtab ← Symtab.add n e s.symtab

let entry_of n =
  try
    Some(Symtab.lookup n s.symtab)
  with
      Not_found → None
```

625. Type from the symbol table.

```
let type_of n =
  match Symtab.lookup n s.symtab with
    | Symtab.Type(c) → Some(c)
```

```
    | _ → None
```

626. Get context for name in symbol table

```
let context_of n =
  match Symtab.lookup n s.symtab with
    | Symtab.State(c) → c
    | _ → raise (Invalid_argument("No context of name " ^ (Name.to_string n)))
```

627. Getting the width of bitvector terms from the signature.

```
let width_of a =
  if Term.is_var a then
    let n = Term.name_of a in
    try
      match Symtab.lookup n s.symtab with
        | Symtab.Arity(i) → Some(i)
        | _ → None
    with
        Not_found → None
  else
    Bitvector.width a
```

628. Resetting all of the global state.

```
let reset () =
  Tools.do_at_reset ();
  s.current ← Context.empty;
  s.symtab ← Symtab.empty;
  s.counter ← 0
```

629. Getting either current context or explicitly specified context.

```
let get_context = function
  | None → s.current
  | Some(n) → context_of n
```

630. Set input and output channels.

```
let set_inchannel ch =
  s.inchannel ← ch

let set_outchannel fmt =
  s.outchannel ← fmt

let flush () = Format.fprintf s.outchannel "@?"
let nl () = Format.fprintf s.outchannel "\n"
```

631. Context.

```
let ctxt_of = function
```

```
  | None → Context.ctxt_of s.current
  | Some(n) → Context.ctxt_of (context_of n)
```

632. Canonization w.r.t current state.

```
let can p =
  Can.atom s.current p

let cant a =
  Can.term s.current a

let sigma f l =
  Context.sigma s.current f l
```

633. Create a fresh name for a state.

```
let rec fresh_state_name () =
  s.counter ← s.counter + 1;
  let n = Name.of_string ("s" ^ (string_of_int s.counter)) in
  try
    let _ = Symtab.lookup n s.symtab in (* make sure state name is really fresh. *)
    fresh_state_name ()
  with
      Not_found →
        n
```

634. Change current state.

```
let save arg =
  let n = match arg with
    | None → fresh_state_name ()
    | Some(n) → n
  in
  let e = Symtab.State s.current in
  s.symtab ← Symtab.add n e s.symtab;
  n

let restore n =
  try

      | _ → raise Not_found
  with
      Not_found → raise (Invalid_argument "Not a state name")

let remove n =
  s.symtab ← Symtab.remove n s.symtab

let forget () =
```

```
  s.current ← Context.empty
```

635. Adding a new fact

```
let process n a =
  let t = (get_context n) in
  let status = Process.atom t a in
  match status with (* Update state and install new name in symbol table *)
    | Process.Ok(t') →
        s.current ← t';
        let n = save None in
        Process.Ok(n)
    | Process.Valid →
        Process.Valid
    | Process.Inconsistent →
        Process.Inconsistent

let valid n a =
  match Process.atom (get_context n) a with
    | Process.Valid → true
    | _ → false

let unsat n a =
  match Process.atom (get_context n) a with
    | Process.Inconsistent → true
    | _ → false
```

636. Accessors.

```
let diseq n a =
  let s = get_context n in
  let a' = Can.term s a in
  try
    Context.d s a'
  with
      Not_found → Term.Set.empty

let cnstrnt n a =
  let s = get_context n in
  let a' = Can.term s a in
  try
    Some(Context.cnstrnt s a')
  with
      Not_found → None
```

637. Applying maps.

```
let find n i x = Context.find i (get_context n) x
let inv n i b = Context.inv i (get_context n) b
```

```
let use n i = Context.use i (get_context n)
```

638. Solution sets.

```
let solution n i =
  Solution.fold
    (fun x (a, _) acc → (x, a) :: acc)
    (Context.eqs_of (get_context n) i)
    []
```

639. Variable partitioning.

```
let partition () =
  Term.Map.fold
    (fun x ys acc →
       (x, Term.Set.elements ys) :: acc)
    (V.partition (Context.v_of s.current))
    []
```

640. Solver.

```
let solve i (a, b) =
  try
    let e = Fact.mk_equal a b None in
      List.map (fun e' →
                  let (x, b, _) = Fact.d_equal e' in
                    (x, b))
        (Th.solve i e)
  with
    | Exc.Inconsistent → raise(Invalid_argument("Unsat"))
    | Exc.Unsolved → raise(Invalid_argument("Unsolvable"))
```

641. Equality/disequality test.

```
let is_equal a b =
  Can.eq s.current a b

let is_int a =
  try
    let c = Context.cnstrnt s.current a in
      Cnstrnt.dom_of c = Dom.Int
  with
      Not_found → false
```

642. Splitting.

```
let split () = Context.split s.current
```

```

6.52 Module ics

Interface for module Ics.mli

644. Module *Ics*: the application programming interface to ICS for asserting formulas to a logical context, switching between different logical contexts, and functions for manipulating and normalizing terms.

There are two sets of interface functions. The functional interface provides functions for building up the main syntactic categories of ICS such as terms and atoms, and for extending logical contexts using *process*, which is side-effect free.

In contrast to this functional interface, the command interface manipulates a global state consisting, among others, of symbol tables and the current logical context. The *cmd_rep* procedure, which reads commands from the current input channel and manipulates the global structures accordingly, is used to implement the ICS interactor.

Besides functions for manipulating ICS datatypes, this interface also contains a number

of standard datatypes such as channels, multiprecision arithmetic, tuples, and lists.

645. Controls. *reset* clears all the global tables. This does not only include the current context but also internal tables used for hash-consing and memoization purposes. *gc* triggers a full major collection of ocaml's garbage collector. *do_at_exit* clears out internal data structures.

val *reset* : *unit* → *unit*

val *gc* : *unit* → *unit*

val *do_at_exit* : *unit* → *unit*

646. *set_maxloops n* determines an upper number of loops in the main ICS loop. $n < 0$ determines that there is no such bound; this is also the default.

val *set_maxloops* : *int* → *unit*

647. Rudimentary control on trace messages, which are sent to *stderr*. These functions are mainly included for debugging purposes, and are usually not being used by the application programmer. *trace_add str* enables tracing of functions associated with trace level *str*. *trace_add* `"all"` enables all tracing. *trace_remove str* removes *str* from the set of active trace levels, and *trace_reset*() disables all tracing. *trace_get*() returns the set of active trace levels.

val *trace_reset* : *unit* → *unit*
val *trace_add* : *string* → *unit*
val *trace_remove* : *string* → *unit*
val *trace_get* : *unit* → *string list*

648. Channels. *inchannel* is the type of input channels. A channel of name *str* is opened with *in_of_string str*. This function raises *Sys_error* in case such a channel can not be opened. *outchannel* is the type of formatting output channels, and channels of this type are opened with *out_of_string*. *stdin*, *stdout*, and *stderr* are predefined channels for standard input, standard output, and standard error. *flush* flushes the *stdout* channel.

type *inchannel* = *in_channel*
type *outchannel* = *Format.formatter*

val *channel_stdin* : *unit* → *inchannel*
val *channel_stdout* : *unit* → *outchannel*
val *channel_stderr* : *unit* → *outchannel*
val *inchannel_of_string* : *string* → *inchannel*
val *outchannel_of_string* : *string* → *outchannel*

val *flush* : *unit* → *unit*

649. Multi-precision rational numbers. *num_of_int n* injects an integer into this type, *num_of_ints n m*, for $m \neq 0$, constructs a normalized representation of the rational n/m in *q*, *string_of_num q* constructs a string (usually for printout) of a rational number, and

num_of_string s constructs a rational, whenever *s* is of the form `"n/m"` where *n* and *m* are naturals.

type *q*

val *num_of_int* : *int* → *q*
val *num_of_ints* : *int* → *int* → *q*
val *ints_of_num* : *q* → *string* × *string*
val *string_of_num* : *q* → *string*
val *num_of_string* : *string* → *q*

650. Names. *name_of_string* and *name_to_string* coerce between the datatypes of strings and names. These coercions are inverse to each other. *name_eq* tests for equality of names in constant time.

type *name*

val *name_of_string* : *string* → *name*
val *name_to_string* : *name* → *string*
val *name_eq* : *name* → *name* → *bool*

651. Arithmetic constraints. A constraint consists of a domain restriction *Int* or *Real* , a real interval, and a set of disequality numbers. A real number satisfies such a constraint if, first, it satisfies the domain restriction, second, it is a member of the interval, and, third, it is none of the numbers in the disequality set.

cnstrnt_of_string str parses the string *str* according to the nonterminal *cnstrnteof* in module *Parser* (see its specification in file parser.*mly*) and produces the corresponding constraint representation. In contrast, *cnstrnt_input* in parses the concrete syntax of constraints from the input channel in. Constraints *c* are printed to the output channel *out* using *cnstrnt_output out c* and to the standard output using *cnstrnt_pp c*.

For the definition of constraint constructors see Module *Cnstrnt*. *cnstrnt_mk_int*() constructs an integer constraint, *cnstrnt_mk_nat*() a constraint for the natural numbers, *cnstrnt_mk_singleton q* is the constraint which holds only of *q*, *cnstrnt_mk_diseq q* holds for all reals except for *q*, *cnstrnt_mk_oo l h* constructs an open interval with lower bound *l* and upper bound *h*, *cnstrnt_mk_oc l h* is the left-open, right-closed interval with lower bound *l* and upper bound *h*, *cnstrnt_mk_co l h* is the left-closed, right-open interval with lower bound *l* and upper bound *h*, *cnstrnt_mk_cc l h* is the closed interval with lower bound *l* and upper bound *h*.

The intersection of two constraints *c*, *d* is computed by *cnstrnt_inter c d*, that is, a real *q* is in both *c* and *d* iff it is in *cnstrnt_inter c d*.

type *cnstrnt*

val *cnstrnt_of_string* : *string* → *cnstrnt*
val *cnstrnt_input* : *inchannel* → *cnstrnt*
val *cnstrnt_output* : *outchannel* → *cnstrnt* → *unit*
val *cnstrnt_pp* : *cnstrnt* → *unit*

val *cnstrnt_mk_int* : *unit* → *cnstrnt*

val *cnstrnt_mk_nonint* : *unit* → *cnstrnt*
val *cnstrnt_mk_nat* : *unit* → *cnstrnt*
val *cnstrnt_mk_singleton* : *q* → *cnstrnt*
val *cnstrnt_mk_diseq* : *q* → *cnstrnt*
val *cnstrnt_mk_oo* : *q* → *q* → *cnstrnt*
val *cnstrnt_mk_oc* : *q* → *q* → *cnstrnt*
val *cnstrnt_mk_co* : *q* → *q* → *cnstrnt*
val *cnstrnt_mk_cc* : *q* → *q* → *cnstrnt*
val *cnstrnt_mk_lt* : *q* → *cnstrnt*
val *cnstrnt_mk_le* : *q* → *cnstrnt*
val *cnstrnt_mk_gt* : *q* → *cnstrnt*
val *cnstrnt_mk_ge* : *q* → *cnstrnt*

val *cnstrnt_inter* : *cnstrnt* → *cnstrnt* → *cnstrnt*

652. Abstract interval interpretation. A real number x is in *cnstrnt_add c d* iff there are real numbers y in c and z in d such that $x = y + x$. Likewise, x is in *cnstrnt_multq q c* iff there exists y in c such that $x = q \times y$. In constrast to these exact abstract operators, *cnstrnt_mult* and *cnstrnt_div* compute overaprroximations, that is, if x in c and y in d then there exists a z in *cnstrnt_mult c d* (*cnstrnt_div c d*) such that $z = x \times y$ ($z = x/y$).

val *cnstrnt_add* : *cnstrnt* → *cnstrnt* → *cnstrnt*
val *cnstrnt_multq* : *q* → *cnstrnt* → *cnstrnt*
val *cnstrnt_mult* : *cnstrnt* → *cnstrnt* → *cnstrnt*
val *cnstrnt_div* : *cnstrnt* → *cnstrnt* → *cnstrnt*

653. Theories. A theory is associated with each function symbol. These theories are indexed by naturals between 0 and 8 according to the following table

0 Theory of uninterpreted function symbols. 1 Linear arithmetic theory. 2 Product theory. 3 Bitvector theory. 4 Coproducts. 5 Power products. 6 Theory of function abstraction and application. 7 Array theory. 8 Theory of bitvector interpretation(s).

type *th* = *int*

val *th_to_string* : *th* → *string*

654. Function symbols. These are partitioned into uninterpreted function symbols and function symbols interpreted in one of the builtin theories. For each interpreted function symbol there is a recognizer function *is_xxx*. Some values of type *sym* represent families of function symbols. The corresponding indices can be obtained using the destructor *d_xxx* functions (only after checking that *is_xxx* holds.

type *sym*

val *sym_is_uninterp* : *sym* → *bool*
val *sym_is_interp* : *th* → *sym* → *bool*

655. *sym_eq* tests for equality of two function symbols.

val $sym\_eq : sym \to sym \to bool$

656. *sym_cmp* provides a total ordering on function symbols. It returns a negative integer if $s < t$, 0 if s is equal to t, and a positive number if $s > t$.

val $sym\_cmp : sym \to sym \to int$

657. Arithmetic function symbols are either numerals, addition, or linear multiplication.

val $sym\_is\_num : sym \to bool$
val $sym\_d\_num : sym \to q$

val $sym\_is\_add : sym \to bool$

val $sym\_is\_multq : sym \to bool$
val $sym\_d\_multq : sym \to q$

Symbols interpreted in the theory of products.

val $sym\_is\_tuple : sym \to bool$

val $sym\_is\_proj : sym \to bool$
val $sym\_d\_proj : sym \to int \times int$

658. Symbols interpreted in the theory of coproducts.

val $sym\_is\_inl : sym \to bool$
val $sym\_is\_inr : sym \to bool$
val $sym\_is\_outl : sym \to bool$
val $sym\_is\_outr : sym \to bool$

659. Symbols in the bitvector theory.

val $sym\_is\_bv\_const : sym \to bool$

val $sym\_is\_bv\_conc : sym \to bool$
val $sym\_d\_bv\_conc : sym \to int \times int$

val $sym\_is\_bv\_sub : sym \to bool$
val $sym\_d\_bv\_sub : sym \to int \times int \times int$

val $sym\_is\_bv\_bitwise : sym \to bool$
val $sym\_d\_bv\_bitwise : sym \to int$

660. Symbols from the theory of power products.

val $sym\_is\_mult : sym \to bool$

val $sym\_is\_expt : sym \to bool$

661. Symbols from the theory of function abstraction and application.

val $sym\_is\_apply : sym \to bool$
val $sym\_d\_apply : sym \to cnstrnt\ option$

val *sym_is_abs* : *sym* → *bool*

662. Symbols from the theory of arrays.

val *sym_is_select* : *sym* → *bool*

val *sym_is_update* : *sym* → *bool*

663. Symbols from the theory of arithmetic interpretations of bitvectors.

val *sym_is_unsigned* : *sym* → *bool*

664. Terms. Terms are either variables, application of uninterpreted functions, or interpreted constants and operators drawn from a combination of theories..

term_of_string parses a string according to the grammar for the nonterminal *termeof* in module *Parser* (see its specification in file parser.*mly*) and builds a corresponding term. Similary, *term_input* builds a term by reading from an input channel.

term_output out a prints term *a* on the output channel *out*, and *term_pp a* is equivalent to *term_output stdout a*.

Terms are build using constructors, whose names are all of the form *mk_xxx*. For each constructor *mk_xxx* there is a corresponding recognizer *is_xxx* which reduces to true if its argument term has been built with the constructor *mk_xxx*. Moreover, for each constructor *mk_xxx*} above there is a corresponding desctructor *d_xxx* for analyzing the components of such a constructor term.

type *term*

val *term_of_string* : *string* → *term*
val *term_to_string* : *term* → *string*
val *term_input* : *inchannel* → *term*
val *term_output* : *outchannel* → *term* → *unit*
val *term_pp* : *term* → *unit*

665. Equality and Comparison. Comparison *cmp a b* returns either -1, 0, or 1 depending on whether *a* is less than *b*, the arguments are equal, or *a* is greater than *b* according to the builtin term ordering (see *Term.*(<<<)). *term_eq a b* is true iff if *term_cmp a b* returns 0.

val *term_eq* : *term* → *term* → *bool*
val *term_cmp* : *term* → *term* → *int*

666. Given a string *s*, *term_mk_var s* constructs a variable with name *s* and *term_mk_uninterp s al* constructs an application of an uninterpreted function symbol *s* to a list of argument terms. If *s* is any of the builtin function symbols specified in module *Builtin*, the builtin simplifications are applied to this application.

val *term_mk_var* : *string* → *term*

val *term_mk_uninterp* : *string* → *term list* → *term*

667. Arithmetic terms include rational constants built from *term_mk_num q*, linear multiplication *term_mk_multq q a*, addition *term_mk_add a b* of two terms, n-ary addition

term_mk_addl al of a list of terms *al*, subtraction *term_mk_sub a b* of term *b* from term *a*, negation *term_mk_unary_minus a*, multiplication *term_mk_mult a b*, and exponentiation *term_mk_expt n a*. These constructors build up arithmetic terms in a canonical form as defined in module *Arith*. *term_is_arith a* holds iff the toplevel function symbol of *a* is any of the function symbols interpreted in the theory of arithmetic.

val *term_mk_num* : *q* → *term*
val *term_mk_multq* : *q* → *term* → *term*
val *term_mk_add* : *term* → *term* → *term*
val *term_mk_addl* : *term list* → *term*
val *term_mk_sub* : *term* → *term* → *term*
val *term_mk_unary_minus* : *term* → *term*

val *term_is_arith* : *term* → *bool*

668. Tuples are built using the *mk_tuple* constructor, and projection of the *i*-th component of a tuple *t* of length *n* is realized using *mk_proj i n t*.

val *term_mk_tuple* : *term list* → *term*
val *term_mk_proj* : *int* → *int* → *term* → *term*

669. Boolean constants.

val *term_mk_true* : *unit* → *term*
val *term_mk_false* : *unit* → *term*

val *term_is_true* : *term* → *bool*
val *term_is_false* : *term* → *bool*

670. Bitvectors

val *term_mk_bvconst* : *string* → *term*
val *term_mk_bvsub* : (*int* × *int* × *int*) → *term* → *term*
val *term_mk_bvconc* : *int* × *int* → *term* → *term* → *term*
val *term_mk_bwite* : *int* → *term* × *term* × *term* → *term*
val *term_mk_bwand* : *int* → *term* → *term* → *term*
val *term_mk_bwor* : *int* → *term* → *term* → *term*
val *term_mk_bwnot* : *int* → *term* → *term*

671. Coproducts.

val *term_mk_inj* : *int* → *term* → *term*
val *term_mk_out* : *int* → *term* → *term*

672. Set of terms.

type *terms*

673. Atoms. *atom_mk_true*() is the trivially true atom, *atom_mk_false*() is the trivially false atom, and given terms *a*, *b*, the constructor *mk_equal a b* constructs an equality constraint, *mk_diseq a b* a disequality constraint, and *atom_mk_in a c* constructs a membership constraint for *a* and a arithmetic constraint *c*. Atoms are printed to *stdout* using *atom_pp*.

type *atom*

val *atom_pp* : *atom* → *unit*

val *atom_of_string* : *string* → *atom*
val *atom_to_string* : *atom* → *string*

val *atom_mk_equal* : *term* → *term* → *atom*
val *atom_mk_diseq* : *term* → *term* → *atom*
val *atom_mk_in* : *cnstrnt* → *term* → *atom*
val *atom_mk_true* : *unit* → *atom*
val *atom_mk_false* : *unit* → *atom*

674. Derived atomic constraints. *atom_mk_int t* restricts the domain of interpretations of term *t* to the integers. Similarly, *atom_mk_real* restricts its argument to the real numbers. *atom_mk_lt a b* generates the constraint `'a'` $<$ `'b'`, *atom_mk_le a b* yields `'a'` $\leq$ `'b'`, *atom_mk_gt a b* yields `'a'` $>$ `'b'`, and *atom_mk_ge a b* yields `'a'` $\geq$ `'b'`.

val *atom_mk_real* : *term* → *atom*
val *atom_mk_int* : *term* → *atom*
val *atom_mk_nonint* : *term* → *atom*

val *atom_mk_lt* : *term* → *term* → *atom*
val *atom_mk_le* : *term* → *term* → *atom*
val *atom_mk_gt* : *term* → *term* → *atom*
val *atom_mk_ge* : *term* → *term* → *atom*

675. Solution sets.

type *solution*

val *solution_apply* : *solution* → *term* → *term*

val *solution_find* : *solution* → *term* → *term*

val *solution_inv* : *solution* → *term* → *term*

val *solution_mem* : *solution* → *term* → *bool*

val *solution_occurs* : *solution* → *term* → *bool*

val *solution_use* : *solution* → *term* → *terms*

val *solution_is_empty* : *solution* → *bool*

676. Logical context. An element of type *state* is a logical context with *state_empty* the empty context. *state_eq s1 s2* is a constant-time predicate for testing for identity of two states. Thus, whenever this predicate holds its arguments states are equivalent, but not necessarily the other way round. Logical contexts are printed using *state_pp*. The set of atoms in a context *s* are obtained with *state_ctxt_of s*.

type *context*

val *context_eq* : *context* → *context* → *bool*

val *context_empty* : *unit* → *context*

val *context_ctxt_of* : *context* → *atom list*

val *context_u_of* : *context* → *solution*

val *context_a_of* : *context* → *solution*

val *context_t_of* : *context* → *solution*

val *context_bv_of* : *context* → *solution*

val *context_pp* : *context* → *unit*

val *context_ctxt_pp* : *context* → *unit*

677. Builtin simplifying constructors.

val *term_mk_unsigned* : *term* → *term*

val *term_mk_update* : *term* → *term* → *term* → *term*
val *term_mk_select* : *term* → *term* → *term*

val *term_mk_div* : *term* → *term* → *term*

val *term_mk_mult* : *term* → *term* → *term*
val *term_mk_multl* : *term list* → *term*
val *term_mk_expt* : *int* → *term* → *term*
(∗ *term_mk_expt n x* represent $x \hat{} n$. ∗)

val *term_mk_apply* : *term* → *term list* → *term*

val *term_mk_arith_apply* : *cnstrnt* → *term* → *term list* → *term*

678. The operation *process s a* adds a new atom *a* to a logical context *s*. The codomain of this function is of type *status*, elements of which represent the three possible outcomes of processing a proposition: 1. the atom *a* is inconsistent in *s*, 2. it is valid, or, 3., it is satisfiable but not valid. In the third case, a modified state is obtained using the destructor *d_consistent*.

type *status*

val *is_consistent* : *status* → *bool*
val *is_redundant* : *status* → *bool*
val *is_inconsistent* : *status* → *bool*

val *d_consistent* : *status* → *context*

val *process* : *context* → *atom* → *status*

679. Suggesting finite case split.

val *split* : *context* → *atom list*

680. Canonization. Given a logical context *s* and an atom *a*, *can s a* computes a semi-canonical form of *a* in *s*, that is, if *a* holds in *s* it returns *Atom.True*, if the negation of *a*

holds in s then it returns *Atom.False*, and, otherwise, an equivalent normalized atom built up only from variables is returned. The returned logical state might contain fresh variables.

val *can* : *context* → *atom* → *atom*

681. Given a logical context s and a term a, *cnstrnt* s a computes the best possible arithmetic constraint for a in s using constraint informatin in s and abstraction interval interpretation. If no such constraint can be deduced, *None* is returned.

val *cnstrnt* : *context* → *term* → *cnstrnt option*

682. An imperative state *istate* does not only include a logical context of type *state* but also a symbol table and input and output channels. A global *istate* variable is manipulated and destructively updated by commands.

683. Initialization. *init* n sets the verbose level to n. The higher the verbose level, the more trace information is printed to *stderr* (see below). There are no trace messages for $n = 0$. In addition, initialization makes the system to raise the *Sys.Break* exception upon user interrupt ^C^C. The *init* function should be called before using any other function in this API.

val *init* : *int* × *bool* × *string* × *inchannel* × *outchannel* → *unit*

684. *cmd_eval* reads a command from the current input channel according to the grammar for the nonterminal *commandeof* in module *Parser* (see its specification in file parser.*mly*), the current internal *istate* accordingly, and outputs the result to the current output channel.

val *cmd_rep* : *unit* → *unit*

685. Sleeping for a number of seconds.

val *sleep* : *int* → *unit*

686. Lists.

val *is_nil* : α *list* → *bool*
val *cons* : α → α *list* → α *list*
val *head* : α *list* → α
val *tail* : α *list* → α *list*

687. Pairs. *pair* a b builds a pair (a, b) and *fst* (*pair* a b) returns a and *snd* (*pair* b a) returns b.

val *pair* : α → β → $\alpha \times \beta$
val *fst* : $\alpha \times \beta$ → α
val *snd* : $\alpha \times \beta$ → β

688. Triples. Accessors for triples (a, b, c).

val *triple* : α → β → γ → $\alpha \times \beta \times \gamma$
val *fst_of_triple* : $\alpha \times \beta \times \gamma$ → α

val *snd_of_triple* : $\alpha \times \beta \times \gamma \rightarrow \beta$
val *third_of_triple* : $\alpha \times \beta \times \gamma \rightarrow \gamma$

689. Quadruples. Accessors for quadruples (a, b, c, d).

val *fst_of_quadruple* : $\alpha \times \beta \times \gamma \times \delta \rightarrow \alpha$
val *snd_of_quadruple* : $\alpha \times \beta \times \gamma \times \delta \rightarrow \beta$
val *third_of_quadruple* : $\alpha \times \beta \times \gamma \times \delta \rightarrow \gamma$
val *fourth_of_quadruple* : $\alpha \times \beta \times \gamma \times \delta \rightarrow \delta$

690. Options. An element of type α *option* either satisfies the recognizer *is_some* or *is_none*. In case, *is_some* holds, a value of type α can be obtained by *value_of*.

val *is_some* : α *option* $\rightarrow$ *bool*
val *is_none* : α *option* $\rightarrow$ *bool*

val *value_of* : α *option* $\rightarrow \alpha$

Module Ics.ml

691. let *init* $(n,\ pp,\ eot,\ inch,\ outch) =$

```
  Istate.initialize pp eot inch outch;
  if n = 0 then
    Sys.catch_break true (*s raise Sys.Break exception upon *)
                                                (*s user interrupt. *)

Acknowledgements. The algorithms and data structures underlying ICS have been developed by N. Shankar and Harald Rueß. The core ICS code is by Harald Rueß and Jean-Christophe Filliâtre, and the Lisp interface has been developed by Sam Owre, Harald Rueß, and Jean-Christophe Filliâtre. The GMP ocaml interface was originally written by David Monniaux, and adjusted for use with `ocaml 3.00` by Jean-Christophe Filliâtre. Leonardo de Moura wrote the simulator in Appendix 2.

This document has been automatically produced from the source code using the literate programming tool ocamlweb[2].
